In Kibale N. P., *G. matschiei* most often uses small (<5 cm circumference) supports (74%), followed by medium-sized (>5 cm to <25 cm) supports (25%). Large supports (>25 cm) used less than 1% of the time ($n = 527$). Oblique supports most frequently used (51%), followed by vertical ($>60^\circ$) supports (27%) and horizontal ($<30^\circ$) supports (22%) ($n = 543$). *Galago matschiei* spends more time in the mid-canopy (54%) than in the lower canopy (33%) or upper canopy (13%) ($n = 484$; Off & Gebo 2005).

In Kibale N. P., at first encounter, *G. matschiei* were on peripheral branches of the tree (86%, $n = 6$) and on central supports only once (14%, $n = 1$; Weisenseel *et al.* 1993). In Mabira F. R. uses all strata of the forest from 1 to 12 m, with 45% of the sightings at 2.5–4.5 m ($n = 11$). At Buhoma, Bwindi N. P., in near primary forest, 43% at 0–7 m, 19% at 7.5–14.5 m and 38% >15 m ($n = 21$). At Kanyanchu, Kibale N. P., 21% at 0–7 m, 43% at 7.5–14.5 m and 36% >15 m ($n = 23$; Ambrose 2002).

Diet poorly known, but insects (e.g. moths, caterpillars, beetles), fruits, flowers and gums eaten (Rahm 1966, Kingdon 1997, Ambrose 2006). Gum appears to be a dry-season food as Kingdon (1971) recorded insects only during the Nov rains while fruit and resins were the only foods in the Feb dry season in spite of *G. thomasi* feeding on insects only in the same forests during the same month. In Jul (later in the wet season) Kingdon found a *G. matschiei* feeding equally on fruit, resin, caterpillars and small beetles. Rahm (1966) recorded insects as the diet of a specimen collected in Sep.

Social and Reproductive Behaviour Largely solitary, but aggregations not uncommon. The loud, advertising call of *G. matschiei* is the 'churr' (= 'bark' = 'woo'), which is a single unit call repeated at regular, frequent intervals – often numerous times during a calling bout. The 'churr' may facilitate mate recognition, inter-individual cohesion, spacing of strangers and maintenance of territories. Other calls include the 'staccato-yap', 'grunt-yap' and 'screech-yap' alarm calls. Details and oscillograms of some of these calls are presented in Zimmermann

(1990), Bearder *et al.* (1995) and Ambrose (2000, 2006). Does not give 'crescendo' or 'buzz' calls (Bearder *et al.* 1995).

Mothers use their mouths to carry their infant. They also 'park' their infants, leaving them on branches outside their nest-holes while foraging (Ambrose 2006, Bearder *et al.* 2003). In Kibale N. P., Off & Gebo (2005) observed up to 11 individuals emerge on any given night from high in the canopy of a *Celtis durandii* tree. They then followed a predictable route each night off deeper into the forest.

Reproduction and Population Structure Few data but there may be a breeding peak in Nov–Dec (Kingdon 1971).

Predators, Parasites and Diseases No information. Probable predators, especially of young in nests, are genets *Genetta* spp., Two-spotted Palm Civets *Nandinia binotata*, monkeys (*Cercopithecus*, *Allochrocebus*, *Papio* spp.), Robust Chimpanzees *Pan troglodytes* and large, tree-living snakes. Fraser's Eagle-Owl *Bubo poensis* is broadly sympatric with *G. matschiei*. Small galagos give long bouts of loud alarm calls when they detect the presence of *B. poensis* (T. Butynski pers. comm.). It is likely that *B. poensis* is a major predator of all species of small galago within its extensive geographic range – including *G. matschiei*.

Conservation IUCN Category (2012): Least Concern. CITES (2012): Appendix II.

The mid-altitude, montane and bamboo forests that provide habitat for *G. matschiei* are on some of the best soils in Africa for growing crops. In addition, rainfall is reliable and human disease is relatively low in these areas. As such, a large proportion of former habitat for *G. matschiei* has been destroyed, especially over the past 100 years. The habitat that remains is often surrounded by a high human population density (>300 people/km²) and, as such, is becoming increasingly encroached upon in many places, degraded and fragmented. While viable populations of *G. matschiei* probably exist in over a dozen forests (e.g. Kibale N. P., Bwindi Impenetrable N. P., Kahuzi-Biega N. P. and Nyungwe N. P.), these populations are now isolated from one another with no chance for inter-breeding.

GENUS *Euoticus* Needle-clawed Galagos

Euoticus Gray, 1863. Proc. Zool. Soc. Lond. 1863: 140.

There are two, allopatric, species of needle-clawed galagos: Southern Needle-clawed Galago *Euoticus elegantulus* and Northern Needle-clawed Galago *Euoticus pallidus*, with a restricted range in the Bight of Bénin, between the Niger and Congo Rivers. These gum-eating galagos inhabit both primary and secondary forests where they show preference for travelling in the canopy. Within the Biafran region their local distribution seems to be determined by the abundance of their preferred food plants, notably *Albizia*, *Newtonia* and *Entada* spp.

These are long-limbed, woolly, arboreal galagos with a short, blunt muzzle and large, pale orange eyes. There are prominent rims surrounding the eyes, a feature that derives from reinforced bony margins around the orbits. Hands and feet are large in proportion to the body. Keels on the nails of the hands and feet end in sharp points. These are adaptations to securing a firm, spread-eagled attachment to the larger branches and trunks that provide their main diet, gums. The gut shows specializations that are not found in other galagos and are thought to be linked with their dietary specialization in tree exudates (Hill 1953). The dental ‘comb’ is very procumbent and made up of greatly elongated lower incisors that have sharp blades on their outer edges; second premolars also exhibit elongation and ‘blading’. These elaborations suggest some ability to enlarge ready-made wounds in bark, but are insufficiently robust to initiate direct wounding of well-barked trees or lianas. Since several important food trees have a wide distribution in Africa, the restricted distribution of these galagos may well be governed by the presence of bark-wounding animals that make gum flow in sufficient and reliable quantities to satisfy the galago’s year-round requirements. Anomalures, cicadas and bark-boring beetles are likely to be major sources of bark-wounding.

This is the only group of galagos in which the nipples have been reduced to one pair. Bearder *et al.* (1995) showed that *Euoticus* used distinctive, loud ‘clicking’ calls that are brief and irregular. They also make characteristic ‘screeches’, ‘yaps’ and a bird-like ‘kwee’. These calls are unlike the calls of any other galago species or genus, further reinforcing the general recognition of these as a very distinctive type of galago.

The taxonomic history of this genus is long, complex and still controversial. Leconte first described *E. elegantulus* as ‘*Microcebus*

Lateral, palatal and dorsal views of skull of Southern Needle-clawed Galago *Euoticus elegantulus* adult.

elegantulus’ in 1857, mistakenly conflating this West African galago with the Madagascan mouse-lemurs. Gray (1863) coined the name *Euoticus* and Schwarz (1931a) regarded this as the only genus distinct from *Galago*. Comparing the detailed anatomy of *elegantulus* and the Spectacled Lesser Galago *Galago matschiei* (then generally called *inustus*), Kingdon (1971) regarded the latter as intermediate between the *Galago senegalensis/moholi* Group and *Euoticus*. He suggested that all the needle-clawed species might have originated with a return to forest-dwelling by a population of savanna galagos during past humid periods (positing that gum-eating might have evolved in savannas first

as a means of buffering seasonal shortages). This phylogenetic change of habitat was seen as driven by the exploitation of a previously under-utilized, gum-eating niche within the equatorial forests. Haltenorth & Diller (1977) treated *Euoticus* as a subgenus of *Galago* and went so far as to characterize *matschiei* (synonym *inustus*) as an eastern form 'Östlicher Kielnagelgalago' of the western 'Westlicher Kielnagelgalago' *G. elegantulus*.

More recently the prominent orbits, point-keeled nails and gummivorous diet of *G. matschiei* have tended to be dismissed as convergent attributes without taxonomic significance. A molecular study by Masters *et al.* (2007) has rekindled this debate by showing that *Euoticus* and *senegalensis/moholi* cluster with *matschiei* (*inustus*) in a genetic grouping that is separate from all other galagos. These authors place *matschiei* and *elegantulus* in more basal positions than the savanna species, implying that contemporary *senegalensis/moholi* are the more derived. Stiner & Turmelle (2003) also provide data in support of *Euoticus* as the most basal radiation within Galagidae and as an exclusive genus.

While it is obvious that *senegalensis/moholi* have made the deepest excursions into dry, strongly seasonal (mainly acacia) woodlands, it is equally obvious that *elegantulus/pallidus* and *matschiei* both show substantially greater anatomical and, perhaps, physiological specialization than the savanna species. It is therefore likely that a common ancestor for the entire cluster was a relatively generalized, gum-eating galago and that all three lineages have elaborated different permutations of specialization in ecology, diet and anatomy.

The taxonomic status of *matschiei* within the cluster remains problematic. It can be treated (as Haltenorth & Diller did in 1977), as an eastern form of *Euoticus*, or (the course provisionally followed here) included in *Galago* while acknowledging its likely, but distant, affinities with *Euoticus*.

In the field the two acknowledged species of *Euoticus* can be identified by peculiar colouring, a fast, running gait along branches, and short, blunt muzzles. The two species are distinct, but have traditionally been regarded as subspecies of a single species. Their colour, skulls and teeth readily distinguish them:

E. elegantulus: bright foxy red above, contrasting strongly with the grey-white underside. Nasal bones become wider anteriorly. Upper central incisors with only a narrow gap between them; P² very strongly elongated and caniniform; P₂ simple, with at most a small talonid; M₃ five-cusped. Occurs south of the Sanaga R.

E. pallidus: pale reddish, buffy or reddish-grey, much greyer on arms, shoulders, neck and tail; dorsal stripe dark grey-brown; face light buff; underside yellowish-white or greyish-white, with comparatively little contrast to upper side. Nasal bones become wider posteriorly. Upper central incisors with wide gap between them; P² and P₂ less specialized, the latter with a strong talonid; upper first and second molars with prominent mesostyle; M₃ four-cusped. Occurs north and north-west of the Sanaga R. and on Bioko I.

There is considerable variation, apparently geographic, within *E. elegantulus*. Animals from the Belinga District, NE Gabon, are smaller than those from the coast, and those from inland regions of Congo are noticeably dark. Many individuals have a white tail-tip. *Euoticus pallidus* is always small in size, and does not have a white tail-tip. Compared to *E. p. talboti* on the mainland, *E. p. pallidus* is darker and greyer, dorsal stripe and underside are greyish, and black eye-rings extend onto the nose so that the white inter-orbital stripe does not extend so far towards the forehead. Underside of *E. p. talboti* is yellowish-white.

Jonathan Kingdon & Colin P. Groves

Euoticus elegantulus SOUTHERN NEEDLE-CLAWED GALAGO (ELEGANT GALAGO)

Fr. Galago mignon du sud; Ger. Südlicher Kielnagelgalago

Euoticus elegantulus (Le Conte, 1857). Proc. Acad. Nat. Sci. Phila. 9: 10. Ndjola, Ogooué R., Gabon.

Taxonomy Monotypic species. Originally placed by Leconte (1857) in genus *Galago*, Gray (1863) considered this species to belong in subgenus *Euoticus*. Schwarz (1931a) and Hill (1953) considered that this represented a distinct genus. Subsequent authors have disagreed. Two subspecies formerly described: *G. e. elegantulus* (Leconte 1857) and *G. e. pallidus* (Gray 1863). Groves (1989) elevated these to full species and placed them in the genus *Euoticus*. Recent genetic analysis places the needle-clawed galagos in a clade with the lesser galagos but separated from them by a considerable genetic distance (Bayes 1998), which supports their taxonomic distinctiveness. Synonyms: *apicalis*, *tonsor*. Chromosome number: not known.

Description Medium-sized galago with a bright orange dorsum and pale, silvery-grey ventrum. Adult ♀ like adult ♂ in pattern and colouration of pelage. Orange of dorsum can be darker on the shoulders and upper dorsum and sometimes extends part way across the chest forming an incomplete collar. Pale grey of the ventrum extends onto flanks under the fore- and hindlimbs creating a 'saddle'.

Southern Needle-clawed Galago *Euoticus elegantulus*.

Southern Needle-clawed Galago *Euoticus elegantulus* adult.

Ears narrow and comparatively small. Eyes large and oval. Snout relatively blunt for a galago. Pale grey nose-stripe in some individuals. Eye-rings indistinct. Tail long and evenly bushy. Tail colour appears to vary with age. In most adults the base of tail is same colour as dorsum, with the last two-thirds dark grey except for white over the distal 2–3 cm. Juveniles have entirely dark grey tails with a few white hairs at tip.

Geographic Variation One population in S Cameroon without white-tipped tail. Population in the Forêt des Abeilles, south of Ogooué R., S Gabon, has grey dorsum and exhibits regional variation in calls (Ambrose 1999).

Similar Species

Euoticus pallidus. Parapatric or allopatric at Sanaga R. North of Sanaga R. in SW Cameroon. Also in SE Nigeria and on Bioko I. In most populations dorsum is orange-brown or cinnamon with a darker dorsal stripe. Can be distinguished by harsh, long drawn-out screeches.

Distribution Endemic to western central Africa. Rainforest BZ. In forests south of the Sanaga R. in SW Cameroon, Equatorial Guinea (Rio Muni), Gabon, Congo and SW Central African Republic. Range thought to extend to Congo R. and Ubangui R., DR Congo (Nash *et al.* 1989). In Ebom, near Kribi, Dja Reserve and Lobéké Reserve, S. Cameroon, and Makokou, Lopé Reserve and Forêt des Abeilles C Gabon (Ambrose 1999). Four specimens from extreme SW Central African Republic indicate presence east of Sangha R. (Stiner & Turmelle 2003).

Habitat Low- to medium-altitude forest. Primary and secondary forest, including littoral, evergreen, semi-deciduous and deciduous forest. Present from near sea level to at least 700 m (J. Oates pers. comm.). Mean annual rainfall at some sites is 1600–1800 mm

Euoticus elegantulus

(Laclavère 1980, Wilkes 1990, Fimbel & Fimbel 1996). Occupies the canopy strata; at 15–30 ca. 72% of the time ($n = 155$ observations). Not observed below 4 m. Favours Umbrella Tree *Musanga cecropioides* on edge of forest and along roads (Ambrose 1999). In Rio Muni, in shade trees in coffee plantations; often Mimosaceae, presumably because of gums (J. Oates pers. obs.).

Abundance Locally common, but with a patchy distribution related to suitable food trees. Population density estimated at 15–20/km² at Makokou (Charles-Dominique 1977).

Adaptations Nocturnal and arboreal. Claw-like nails enable active movement on broad and smooth supports. Moves freely on tree trunks, runs along branches and is able to make leaps of up to 5 m to a neighbouring tree with some loss of height, or to free fall with outstretched limbs for about 8 m. Toilet-claw and toothcomb used for grooming. Young carried in mother's mouth. Juveniles parked in tree forks, often as low as 5 m, and only ascend if approached (Ambrose 1999).

Foraging and Food Gummivore. Feeds heavily on gum from a limited number of tree and liana species. At Makokou, 80% of gum eaten from one species of liane, *Entada gigas*. The search for gums is the principal activity and an individual will follow the same itinerary each night, visiting each site in sequence at regular times. Gums can be found by smell at 20–30 cm. Tiny droplets are licked or scooped with the toothcomb (Charles-Dominique 1977). Also eat invertebrates such as cicadas, which are caught with the hands (Ambrose 1999). Insects found in stomachs of specimens in Rio Muni (Jewell & Oates 1969b). Fruit occasionally eaten.

Social and Reproductive Behaviour Solitary forager but maintains vocal contact with familiar animals. Gathering call at dawn. Sleeps communally, up to seven individuals may sleep tightly

packed together in the vegetation. Individuals use several sleeping sites but usually within an area of <1 ha (Charles-Dominique 1977). One call-type is common both to *E. elegantulus* and *E. pallidus*: high-pitched single units often repeated in long sequences ('t'ya'). The characteristic call of this species comprises a pattern of relatively low frequency yaps interspersed with rapid, slightly ascending sequences or rattles (Ambrose 1999).

Reproduction and Population Structure Breeding thought to occur throughout the year. Four 'parked' juveniles observed in Dja Reserve in March (Ambrose 1999). Adult weight reached at 8–10 months of age. Almost equal proportion of ♂♂ to ♀♀ at Makokou (Charles-Dominique 1977).

Parasites, Predators and Diseases Predation not reported. Predators probably include pythons *Python* spp. and small arboreal predators such as the Two-spotted Palm Civet *Nandinia binotata* and Central African Linsang *Poiana richardsoni* (Charles-Dominique 1977). No information on diseases.

Conservation IUCN Category (2012): Least Concern. CITES (2012): Appendix II.

Occupies a large area of relatively undisturbed, contiguous forest. Affected by logging in some regions. Occurs at high densities at some sites.

Euoticus pallidus NORTHERN NEEDLE-CLAWED GALAGO (PALLID GALAGO)

Fr. Galago mignon du nord; Ger. Nördlicher Kielnagelgalago

Euoticus pallidus (Gray, 1863). Proc. Zool. Soc. Lond. 1863: 140. Fernando Po (= Bioko I.), Equatorial Guinea.

Northern Needle-clawed Galago *Euoticus pallidus* adult.

Taxonomy Polytypic species. Formerly described as a subspecies of the Elegant Galago *Euoticus elegantulus*, elevated to full species by Groves (1989). Two subspecies are now recognized (Ambrose 1999, Grubb *et al.* 2003). Synonym: *talboti*. Chromosome number: not known.

Description Medium-sized galago with a cinnamon or orange-brown to grey dorsum and pale grey ventrum. Adult ♀ like adult ♂ in pattern and colouration of pelage. Pale grey extends up the sides of the face and onto the flanks by the shoulders and thighs in a saddle-shape. Thin but well-defined brown dorsal stripe in some individuals. This runs from the shoulder blades at least two-thirds of the way down the spine. Eye-rings black. Ears grey. Snout, feet and hands are pink. Tail long and bushy, same colour at base as the dorsum and grading distally to grey.

Geographic Variation

E. p. pallidus Bioko Needle-clawed Galago. Bioko I. Considerably larger than mainland form. Dorsum grey.

E. p. talboti Nigeria Needle-clawed Galago. SW Cameroon and SE Nigeria. Considerably smaller than Bioko I. form. Dorsum cinnamon.

Similar Species

Euoticus elegantulus. Allopatric. South of Sanaga R. in SW Cameroon. In Equatorial Guinea, Gabon, Congo and extreme SW Central African Republic. Most populations have orange dorsum with white tail-tip. Distinguishing call a slightly ascending rapid sequence or 'rattle' interspersed with 'yaps'.

Distribution Endemic to SE Nigeria, SW Cameroon and Bioko I. Rainforest BZ. In forest between lower Niger R. and Sanaga R., SE

Nigeria and SW Cameroon, and on Bioko I., Equatorial Guinea. In SE Nigeria at Elele and Mamu F. R., in SW Cameroon at Korup N. P., Mt Kupé and Mt Cameroon (Malbrant & Maclatchy 1949, Oates & Jewell 1967, Eisentraut 1973, Bearder & Honess 1992, Ambrose 1999, T. Butynski pers. comm.).

Habitat Primary and secondary lowland and montane moist forest. In Nigeria also in riverine swamp forest and tree plantations. On Bioko I., occurs from sea level to ca. 1600 m and where mean annual rainfall ranges 4000–10,000 mm (T. Butynski pers. comm.). On mainland, occurs from near sea level to at least 2000 m where mean annual rainfall is 1500–10,000 mm. On Mt Kupe and Mt Cameroon, SW Cameroon, 1000–2000 m, not on lower slopes. Over the wettest part of the range (i.e. coast of mainland and on Bioko I.) the dry season is Dec–Feb (<50 mm rainfall/month), whereas farther north the dry season is Nov–Mar.

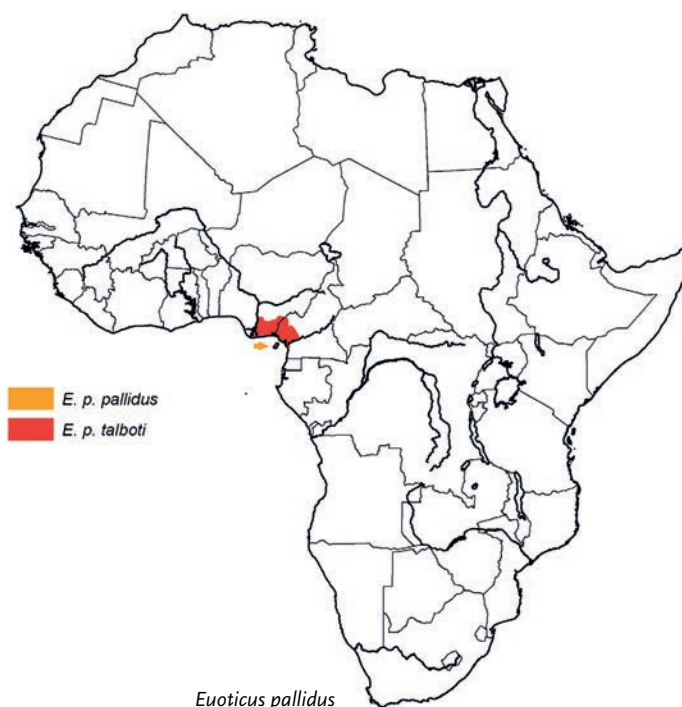

Abundance Uncommon in most locations; rarely encountered. Distribution probably patchy and relates to suitable gum-producing tree species. Uncommon on Bioko I. but regularly observed at specific sites (T. Butynski pers. comm.). At Moka, Bioko I., encountered at the rate of 0.2 ind/h (n = 12; Ambrose & Perkin 2000), 0.3 ind/h (Schlossman 2006), and 0.4 ind/h and 0.3 ind/km (n = 16; Croce (2009)). At most sites on the mainland, Ambrose (1999) recorded ca. 0.2 ind/h (n = 49), but 0.9 ind/h and 1.9 ind/km (n = 96) on Mt Kupé. Encounter rates of 1.4 ind/km (n = 232) in Korup N. P. (Bearder & Honess 1992) and 0.6 ind/km (n = 13) in Mamu F. R. (Jewell & Oates 1969b).

Foraging and Food Gummivore. Forages most often in the canopy; 61% of 63 observations >15 m (Ambrose 1999) but also descends into understorey. At Moka, 100% of 12 encounters with *E. pallidus* were above 5 m, and 83% were above 10 m (Ambrose & Perkin 2000). A second study at Moka yielded a mean height of 9.5 m (5–15 m, n = 10; Croce 2009). Feeds on tree gums that are scooped with the toothcomb and invertebrates that are grabbed with the hands. Sometimes hangs bipedally when catching insects.

Adaptations Moves actively on broad supports and can grip smooth surfaces with claw-like nails. Often descends trunks head first. Makes horizontal leaps between adjoining trees and drops vertically with outstretched limbs, sometimes re-ascending and repeating this behaviour a number of times when agitated. Hollow trees can be used for sleeping sites. Mother carries young in her mouth.

Social and Reproductive Behaviour Solitary forager but sleeps communally. Gives specific gathering call at dawn. Up to four individuals located together at dusk in Cameroon, but 86% (n = 80) of observations were of lone animals. No information on reproductive behaviour. One call-type is common both to *E. elegantulus* and *E. pallidus*: high-pitched single units often repeated in long sequences ('t'ya'). Long, harsh screeches are characteristic of this species.

Reproduction and Population Structure Thought to breed throughout the year. Sanderson (1940) collected pregnant ♀♀ in

Jan, May, Jun and Nov from Cameroon and E Nigeria. Jewell & Oates (1969a) collected a pregnant ♀ in Nov at Mamu, Nigeria. No information on population structure.

Predators, Parasites and Diseases Not studied. One record of Central African Linsang *Poiana richardsoni* killing and eating infant *E. pallidus* on Bioko I. (A. Croce pers. comm.).

Conservation IUCN Category (2012): Least Concern. Endangered as *E. p. pallidus*. CITES (2012): Appendix II.

Fragmented distribution in most habitats and occurs at low densities. Not hunted. Primary threat is habitat loss.

Key References Ambrose 1999; Jewell & Oates 1969a, b; Oates 2011.**Lesley Ambrose & John F. Oates****GENUS *Galagoides*****Dwarf Galagos***Galagoides* A. Smith, 1833. South African Quarterly Journal (1) pt 1: 32.Demidoff's Dwarf Galago *Galagoides demidovii* adult.

This genus must presently be considered as a wastebasket category for the smallest galagos that do not fit into any other genus but for which there are as yet insufficient data to assign them to a separate taxon. On the basis of an extensive cladistic analysis, Groves (2001) considered it unsafe to use this genus and assigned species to *Galago* instead. Extensive convergence or parallelism in animals of similar body size and habitats can easily be mistaken for a close phylogenetic relationship (Masters *et al.* 1994, Masters & Brothers 2002). Indications that further separation will be required come from new molecular evidence (e.g. DelPero *et al.* 2000, Stiner & Turmelle 2003, Roos *et al.* 2004, Masters *et al.* 2007) and comparisons of vocal repertoires (see below).

Grubb *et al.* (2003: 1309) give the following account:

[Osman] Hill (1953) emphasized the distinctiveness of *Galagoides* at a time when it was thought to be monotypic. Other species have since been allocated to the genus. *Galagoides zanzibaricus* was removed from Schwarz's (1931) *Galago senegalensis*, *sensu lato*, while *Galagoides granti*, *G. cocos* and *G. nyasae* were in turn detached from *G. zanzibaricus*. Three

more species have been described since Schwarz's (1931) review, or are waiting to be named. The genus includes small forest species with body mass below 200 g, and with shorter limbs and lighter build than *Galago sensu stricto*. They also differ from *Galago* in characters of the skull and teeth (Groves 1989). Buzz calls are present and calls used to attract companions and repel rivals comprise complex phrases. In contrast, *Galago* spp. do not give buzz calls and their recognition calls are repetitive in bouts of variable length (Bearder *et al.* 1995). Mitochondrial genes show that the percentage sequence divergence in an rRNA gene between *Galago senegalensis* and *Galagoides demidovii* is greater than that between *Galago senegalensis* and *Otolemur*, so *Galagoides* might be a sister taxon of a group including *Galago* and *Otolemur* (Bayes 1998). More information is needed to establish that *Galagoides* is a monophyletic taxon.

Since this was written, more detailed work on DNA sequence analysis shows large genetic distances between a clade linking the two small galagos that are ubiquitous throughout the forests of West and central Africa (Demidoff's Dwarf Galago *Galagoides demidovii* and Thomas's Dwarf Galago *G. thomasi*) and the remaining taxa, including Mozambique Dwarf Galago *G. granti* (DelPero *et al.* 2000, Masters *et al.* 2007), causing these authors to suggest that a new generic diagnosis is required. Similarly, comparative studies of penile morphology among five species of *Galagoides* from the Eastern Arc Mts and coastal forests of Tanzania and Kenya (Perkin 2007) show that the Mountain Dwarf Galago *G. orinus* and Rondo Dwarf Galago *G. rondoensis* diverge considerably from the other species and are probably phylogenetically distinct. These conclusions conform only partially with divergence in vocal repertoires (Bearder *et al.* 1995, Honess 1996b), which divides current members of the genus *Galagoides* into four groups based on broad characteristics of the loud-calls used to attract companions and repel rivals: (1) *G. demidovii* and *G. thomasi* give highly distinctive 'crescendo' calls; (2) *G. cocos* and *G. granti* have unique 'incremental' calls; (3) *G. zanzibaricus* and *G. rondoensis* have 'rolling' calls; and (4) *G. orinus* gives 'scaling' calls.

Galagoides zanzibaricus ZANZIBAR DWARF GALAGO

Fr. Galago de Zanzibar; Ger. Sansibar-Galago

Galagoides zanzibaricus (Matschie, 1893). Sitzb. Ges. Naturf. Fr. Berlin, p. 111. Yambiani, Zanzibar, Tanzania.Zanzibar Dwarf Galago
Galagoides zanzibaricus
zanzibaricus adult.Matundu Dwarf Galago
Galagoides zanzibaricus
udzungwensis adult.

Taxonomy Polytypic species. Taxonomy unresolved. Previously regarded as a subspecies of *Galago senegalensis* (Schwarz 1931a), the specific name was revived by Kingdon (1971). Moved from genus *Galago* to genus *Galagoides* by Olson (1979) and, subsequently, three species split off: Mozambique Dwarf Galago *Galagoides granti*, Malawi Dwarf Galago *Galagoides nyasae*, and Kenya Coast Dwarf Galago *Galagoides cocos* (Honess 1996b, Groves 2001, Grubb *et al.* 2003), based on differences in vocalizations, and in body, penile and hand morphology (Bearder *et al.* 1995, Honess 1996b, Anderson 2000, Groves 2001, Butynski *et al.* 2006, Perkin 2007). Two subspecies recognized: Zanzibar Dwarf Galago *G. zanzibaricus zanzibaricus* and Matundu Dwarf Galago *G. z. udzungwensis* (Honess 1996b, Honess & Bearder 1996, Butynski *et al.* 2006). Note that *udzungwensis* originally given full species status and that the authority for this name is 'Honess 1996', not 'Honess 1997' as stated in Honess & Bearder (1996), Groves (2001) and in Grubb *et al.* (2003). Synonym: *udzungwensis*. Chromosome number: $2n = 36$ (Ying & Butler 1971, De Boer 1973a, b).

Description Small, buffy-grey to greyish-brown galago, with distinctive 'single-unit rolling' advertisement call (Honess 1996b, Butynski *et al.* 2006). Sexes alike in colour and pattern of pelage. Nose-stripe white to cream, broad, from base of rhinarium to just posterior to eyes. Dark patch on either side of muzzle not prominent. Cheeks and chin pale yellow to yellowish-buff. Throat yellow wash to orange-buff. Eye-rings indistinct or absent. Ears relatively erect, short, not notably pigmented. Dorsum rufous cinnamon to greyish-brown and buffy-grey. Tail of uniform thickness with relatively sparse hairs (can see skin). Distal ca. 25–35% of tail darker. Ventrums cream to yellowish-buff (Honess 1996b, Butynski *et al.* 2006). Immatures

like adults but with creamy-white throat. Penis is mostly spine covered and cylindrical in shape but expands greatly laterally in the mid-portion where spines are robust and pinnate. The baculum protrudes notably from the glans penis. Immature animals similar in shape but lacking spines (Honess 1996b, Perkin 2007).

Geographic Variation

G. z. zanzibaricus Zanzibar Dwarf Galago. Endemic to Zanzibar I and perhaps Mafia I. Throat washed with yellow. Ventrums pale yellow. Dorsum cinnamon. Tail with at least some rufous (Butynski *et al.* 2006). Baculum does not protrude beyond end of glans. Penile lappets absent. Penis has spines of uniform type (Honess 1996b, Anderson 2000).

G. z. udzungwensis Matundu Dwarf Galago. Endemic to several lowland forests on mainland of Tanzania. Throat orange-buff. Dorsum greyish-brown or buffy-brown. Tail lacks rufous. Ventrums yellowish-buff (Honess 1996b, Butynski *et al.* 2006). Baculum protrudes beyond end of glans. Penile lappets present. Penis lacks spines (Honess 1996b, Anderson 2000).

Similar Species

Galagoides cocos. Possibly slightly sympatric or parapatric with *G. z. udzungwensis* at north end of *G. z. udzungwensis* range. 'Incremental' advertisement call distinctive. Eye-rings prominent. Nose-stripe white, well defined. Patch on either side of muzzle dark and prominent. Ventrums greyish-white. Penis with robust, pinnate spines all along shaft. Baculum does not protrude beyond end of penis. Inside of ears darkens towards the tips. HB slightly longer (mean 157 mm, $n = 43$; range 145–170 mm, $n = 56$; Harcourt & Nash 1986a, Groves 2001, Butynski *et al.* 2006).

Galagoides granti. Probably parapatric with *G. z. udzungwensis* north of Rufiji/Kilombero River System and *G. granti* to south (Honess 1996b, Butynski *et al.* 2006). 'Incremental' advertisement call distinctive. Inside of the ears darkens towards tip and blackish behind. Tail relatively bushy with blackish-brown tip. Forefeet white on lateral surface. Penis thin and pointed, wider dorso-ventrally than laterally. Baculum does not protrude beyond penis tip (Honess 1996b, Anderson 2000, Perkin 2007). Slightly larger, especially the ears (mean 37 mm, $n = [3]17$; range 35–41 mm, $n = [3]22$); (Honess & Bearder 1996, Groves 2001, Butynski *et al.* 2006).

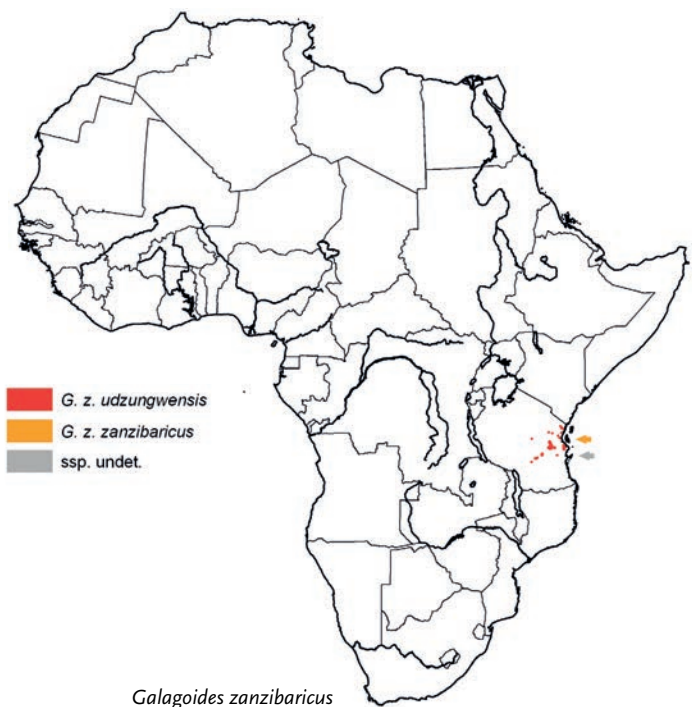

Galagoides orinus. Montane forest species that is sympatric with *G. z. udzungwensis* at 600–900 m. Double or triple unit scaling advertisement call distinctive (Honess 1996b, Perkin 2000b, 2001). Dorsum dark brown. Penis conical, tapering from the tip, with robust pinnate spines at the base (Perkin 2007). About one-third smaller (HB mean 132 mm, 125–138, $n = 4$; WT mean 90 g, 74–98, $n = 3$; Honess & Bearder 1996, Groves 2001, Perkin 2000b, 2004).

Galagoides rondoensis. Coastal forest species. Sympatric in Zareninge F. R., Pugu/Kazimzumbwi Forest Reserves and Pande G. R. on coastal Tanzania (Perkin 2004). Dorsum rich brown. Ventrums creamy-white. Double unit rolling advertisement call distinctive. Tail reddish-orange to greyish-brown, sparsely-haired with unique 'bottle brush' shape, often held in a curled up position when resting (Honess 1996b, Honess & Bearder 1996). Penis thin and flute shaped at distal end, spineless apart from two clusters of robust and pinnate spines beneath tip (Perkin 2007). Much smaller: HB mean 131 mm, 123–137, $n = 7$; WT mean 69 g, 60–73, $n = 7$ (all data from ♂♂).

Distribution Endemic to lowland forests of Tanzania. Somalia-Masai Bushland and Coastal Forest Mosaic BZs. *Galagoides z. zanzibaricus* endemic to Zanzibar I and probably Mafia I. (subspecies pending identification). Absent from Pemba I. *Galagoides z. udzungwensis* endemic to Eastern Arc Mts and coastal forests of mainland Tanzania; from South Pare Mts and East Usambara Mts south to the Rufiji R. and west to the Udzungwa Mts at Kihansi (Honess 1996b, Honess & Bearder 1996, Butynski *et al.* 1998, 2006, Rovero *et al.* 2009).

Habitat *Galagoides z. zanzibaricus* lives in a variety of habitats on Zanzibar I. including bush, low forest, ground-water forest, coconut groves and coral rag thicket (Lumsden & Masters 2001). No part of Zanzibar I. is above 120 m. Mean annual rainfall is ca. 1300 mm (Lumsden & Masters 2001). *Galagoides z. udzungwensis* is found in pristine and degraded, lowland forest from sea-level to 1070 m (Butynski *et al.* 2006). Not found in plantation forest (Honess 1996b, Butynski *et al.* 1998). Common in areas of thick secondary growth and tangles of vines, which may represent sleeping or resting sites and/or areas rich in invertebrate food. At sites where mean annual rainfall is 900–1400 mm in coastal forests (Burgess & Clarke 2000) and to 1700 mm in Kimboza F. R. (Uluguru Mts). Temperatures range 19–27°C (Lovett 1992, Honess 1996b), with temperature extreme of 39°C on Zanzibar (Burgess & Clarke 2000).

Abundance *Galagoides z. zanzibaricus* is widespread on eastern and southern parts of Unguja I. (Zanzibar) where suitable habitat remains. Recent surveys estimate >200 ind/km² (Butynski *et al.* 2006). Densities of *G. z. udzungwensis* highly variable. Common in the lowland Udzungwa Mts where 10.0 animals/h were encountered

Lateral view of skull of Zanzibar Dwarf Galago *Galagoides zanzibaricus* *zanzibaricus* adult.

($n = 29$ h). In contrast, 3.7 animals/h were encountered ($n = 10$ h) in the small (405 ha) Kimboza F. R., and 0.3 and 0.4 animals/h in lowland forest at two sites at Kihansi F. R. ($n = 15$ h and $n = 12$ h). In the Udzungwa Mts, during the 'dusk chorus', up to 20 ind/ha (>500 ind/km²) heard calling at some sites compared to <100 ind/km² at other sites (Butynski *et al.* 1998, 2006).

Adaptations Nocturnal and arboreal. Never observed on the ground (Honess 1996b). Usually forages within 10 m of the ground (up to 49% of observations under 5 m; mean 6.5 m, $n = 159$) and on branches that are 0.5–5 cm in diameter (mean 2.5 cm, $n = 26$) (Honess 1996b). Uses quadrupedal walking and running when moving along the tops of horizontal branches and leaping between more vertical stems and between trees. Observed climbing downwards head first, hanging under branches, and standing on the hindlegs (Honess 1996b). Nests, often two animals together, in tree holes and in tangles of dense vegetation (Honess 1996b, Lumsden & Masters 2001). Nests in tree holes 4–8 m high ($n = 5$) (A. Perkin pers. obs.) and probably dependent on tree-hole availability. Green leaves in nests show teeth marks at the base and some are transported from trees other than the nest tree. Two individuals seen making about ten trips each to collect fresh leaves to line tree hole 8 m up (A. Perkin pers. obs.). Coconut palm *Cocos nucifera* fibre and parts of ferns also found in nests (Lumsden & Masters 2001).

Zanzibar Dwarf Galago *Galagoides zanzibaricus zanzibaricus*.

Foraging and Food Omnivorous. Little information. Diet of fruit and invertebrates, with preference in captivity for invertebrates. Fruits include those of *Trichilia emetica* and *Vitex* sp. Observed to hang upside down to feed on ants on a vine below and taking insects in the leaf litter driven out by army ant columns (A. Perkin pers. obs.). Major feeding bouts are shortly after emergence at dusk, around midnight, and shortly before dawn. Not observed to eat gum in the wild. In captivity will take crickets, grasshoppers and moths; the wings are discarded. Insect prey is ambushed but may be taken with the hands if in flight (P. Honess pers. obs.).

Social and Reproductive Behaviour Predominantly solitary foragers; only 11 of 141 (8%) observations were of pairs. Groups larger than two not observed (Honess 1996b). 'Urine wash' and then rub the sternal gland on a branch (Honess 1996b). Vocal advertisement call is a 'single unit rolling call' often used as a 'gathering call'; it is most commonly given at dusk on emergence before first feeding and before dawn for reassembly of sleeping groups (Honess 1996b, Bearder *et al.* 2003). The single unit rolling call, composed of trilled units that increase then decrease in intensity, is highly variable in length (mean 14.1 units per call (1–46, $n = 2122$) (Honess 1996b). This call is given more frequently than other calls in the vocal repertoire (>90% of calls recorded; Honess 1996b). Other calls, primarily reflecting differing levels of alarm, include the 'buzz', 'rapid whistle', 'descending shriek', 'screech', 'screech-grunt' and 'yap', which may be graded in intensity or given in combination, making a total repertoire of at least 25 loud-calls (Honess, 1996b). Young are parked whilst the mother forages and are carried by mouth (A. Perkin pers. obs.).

Reproduction and Population Structure One or two infants produced. One *G. z. udzungwensis* ♀ caught in Sep 1994 aborted twins the same day, which were subsequently cannibalized (Honess 1996b). Among a sample of adult *G. z. zanzibaricus* on Zanzibar, the ♂ : ♀ ratio was 8 : 22 (Masters *et al.* 1993). Observations of pairs of *G. z. udzungwensis* in tree-hole nests (Honess 1996b) suggest a social system (similar to that of *G. cocos*) of a dispersed monogamy with one adult ♂ in close association with one or two adult ♀♀ (Harcourt & Nash 1986a, Bearder 1987, Harcourt & Bearder 1989). However, Lumsden & Masters (2001) report nest-sharing by up to five *G. z. zanzibaricus* (two adult ♂♂, one subadult ♂, one adult ♀, one subadult ♀).

Predators, Parasites and Diseases No data, but likely to be killed by snakes, owls and mammalian carnivores (e.g. Two-spotted Palm Civet *Nandinia binotata* and genets *Genetta* spp.). No information on parasites or diseases.

Conservation IUCN Category (2012): Least Concern. Endangered as *G. z. zanzibaricus*. CITES (2012): Appendix II.

Major threats are habitat degradation and loss. *Galagoides z. zanzibaricus* mainly confined to S and E Unguja I., Zanzibar (1660 km²), where the most significant areas of habitat remain in Jozani-Chwaka Bay N. P. (3 km²) (Burgess & Clarke 2000). *Galagoides z. udzungwensis* present in several relatively large Forest Reserves and receives most protection in the Udzungwa Mountains N. P., Sadaani N. P. and Amani Nature Reserve.

Galagoides rondoensis RONDO DWARF GALAGO

Fr. Galago de Rondo; Ger. Rondo-Galago

Galagoides rondoensis Honess, 1996. Soc. Biol. Hum. Affairs 61(1): 9. Rondo F. R., 10° 07' S, 39° 23' E, Rondo Plateau, Lindi District, Tanzania.

Rondo Dwarf Galago *Galagoides rondoensis* adult.*Galagoides rondoensis*

Taxonomy Monotypic species. First collected from sites in SE Tanzania (near Newala, Makonde Plateau, in 1953, and Rondo Plateau in 1955) and provisionally identified as Demidoff's Dwarf Galago '*Galago demidovii*' and later '*Galago demidovii orinus*' (Honess 1996b, Lumsden & Masters 2001). First recognized and described as a species, based on differences in vocalizations and morphology, by Honess (1996b) and the formal species description published by Honess (1996a). Note that the authority for the name *Galagoides rondoensis* is 'Honess 1996', not 'Honess 1997' as stated in Honess & Bearder (1996), Groves (2001) and Grubb *et al.* (2003). Subspecies not known. Synonyms: *demidoff*, *demidovii*. Chromosome number: not known.

Description One of Africa's two smallest primates. Little or no sexual dimorphism but pelage colour varies according to the maturity of individuals (see below). Muzzle long and slender, with a narrow, pale nose-stripe extending to the forehead. Area on muzzle between nose-stripe and cheek sparsely haired, with yellowish skin pigmentation in young animals and dark brown in mature animals (A. Perkin pers. obs.). Crown and forehead reddish-brown (in young animals) to dark brown (in mature animals). Ears mostly slate-grey, with yellow pigmentation on the auricular opening and edges. Yellow pigmentation of ears, lips and chin especially marked in young animals. Eye-rings absent (Honess 1996b) or thin and dark. Dorsum rich brown extending onto thighs and forelimbs. Ventral pelage creamy white with some yellow staining on the chest in some individuals.

Tail reddish-orange in immature animals and greyish-brown in mature animals. Sparsely haired until tip where hair is longer, giving

a 'bottle brush' shape unique to *G. rondoensis*. Mature animals have thicker hair on tail than immature animals. Tail often held in a curled-up position when resting (Honess 1996b, Honess & Bearder 1996, Perkin 2003). Penis conical and diagnostic in shape, broadening towards distal end (Honess 1996b, Anderson 2000). In mature ♂♂, where the distal end of penis enlarges, there is a diagnostic small semi-concentric patch of 'robust single pointed spines' (1–2 mm) situated just behind the tip (spine terminology after Dixson 1995 and see Anderson 2000). Rest of penis lacks spines in northern populations but heavy spines at base in southern populations (A. Perkin pers. obs.). In immature ♂♂, or possibly non-breeding ♂♂, spines greatly reduced or not present (A. Perkin pers. obs.). The species-specific advertising call, a double unit 'rolling' call, is diagnostic (Honess 1996b, Honess & Bearder 1996).

Geographic Variation No subspecies described but there are differences in call structure and penile morphology between southern nominate population and northern populations (A. Perkin pers. obs.). Limited data (see Measurements) suggest that *G. rondoensis* of the nominate population is smaller than animals of northern populations.

Similar Species

Galagoides zanzibarcus udzungwensis. Sympatric in Zareninge F. R., Pugu/Kazimzumbwi F. R. and Pande G. R. on coastal Tanzania. Larger by ca. 100–150%, greyish-brown dorsum, broad nose-stripe, tail not bushy, tail hairs wiry, penile spine patterns and species-specific advertisement call, the single unit 'rolling' call, diagnostic (Honess 1996b, Honess & Bearder 1996, Bearder 1999, Perkin 2003).

Galagoides granti. Sympatric in Rondo F. R., Litipo F. R. and Ziwani F. R., coastal Tanzania. Larger by ca. 100–150%, dorsum brown, tail not bushy, ears large and blackish. Penile spine patterns diagnostic, as is species-specific ‘incremental’ advertising call (Honess 1996b, Honess & Bearder 1996, Perkin 2003).

Distribution Coastal Forest Mosaic BZ. Endemic to and discretely distributed in six small moist forests in coastal Tanzania: Zarenige F. R. (06°05′ S, 38°23′ E) (Perkin 2000a), Pande G. R. (06°25′ S, 39°03′ E), Pugu/Kazimzumbwi F. R. (06°32′ S, 39°03′ E) (Perkin 2003, 2004), Rondo F. R. (10°06′ S, 39°06′ E), Litipo F. R. (10°01′ S, 39°17′ E) and Ziwani F. R. (10°13′ S, 39°09′ E) (Honess 1996b, Honess & Bearder 1996).

Habitat Occurs in East African coastal dry forest and mist-fed forest, and East African coastal scrub forest within the East African Zanzibar–Inhambane coastal forest belt *sensu* Clarke & Sorensen (2000). Found only in forest patches between 100 and 900 m asl that are wetter than the surrounding habitats (mean annual rainfall 936–1110 mm). Often associated with liana tangles around tree-falls.

Abundance Sight and trap data indicate *G. rondoensis* is locally common but has a highly variable distribution within and among forests. In Pande G. R. densities estimated at 3–6 ind/ha (Perkin 2003). Four individuals trapped in one night in Pugu F. R. in a 0.5 ha plot (Perkin 2004). Encounter rates (number of animals seen or heard per survey hour) range 3–10 animals/h in Pande G. R. and Pugu/Kazimzumbwi F. R. (Perkin 2003, 2004), and 3.9 ind/h in Rondo F. R. (Honess 1996b).

Adaptations Nocturnal and arboreal. Nests for daytime sleeping are in thick liana tangles normally 10–30 m above the ground. Three animals seen to occupy a flat leafy nest only 5 m off the ground in Rondo F. R. After leaving the nest at dusk most time is spent in the forest understorey (less than 3 m off the ground) (Honess 1996b). Locomotion is mainly vertical, clinging to thin stems (less than 5 cm diameter) and leaping. Seen hindleg-hopping on ground to cross small gaps, including single-lane tracks (<3 m), quadrupedal running on horizontal supports and running head-down down tree trunks. Jumps down to pounce on prey in leaf litter before jumping back immediately to a vertical support. Tail often held tightly curled up at rest but unfurled during locomotion. Utilizes a combination of hearing, sight and olfactory senses to locate prey, communicate with conspecifics and to detect potential predators. Will mob potential predators with intense bouts of alarm-calling.

Foraging and Food Omnivorous. Individuals mostly forage alone, leaping quickly from stem to stem to find food items. Insects make up a large proportion of the diet, with proportionately less fruit and gum than taken by larger galagos. When active, spends much time feeding in the understorey and leaf litter layer (Honess 1996b, Bearder *et al.* 2003, Perkin 2003). Often jumps to the ground to take invertebrates, particularly insects fleeing army ant columns. In Pugu/Kazimzumbwi F. R. up to four individuals seen together feeding next to an ant column, sometimes with Zanzibar Dwarf Galago *Galagoides zanzibaricus* (A. Perkin pers. obs.). Stomach analysis of three individuals in Rondo F. R. revealed remains of an unidentified

Lateral and palatal views of skull of Rondo Dwarf Galago *Galagoides rondoensis* adult.

red fruit (Lumsden & Masters 2001). In Pugu/Kazimzumbwi F. R. nectar and flowers are eaten. Entered traps baited with bananas and palm wine and often eat much of the banana.

Social and Reproductive Behaviour The limited data available suggest *G. rondoensis* is solitary or associates in small groups. Three individuals seen nesting together and up to four in loose groups when foraging. In Rondo F. R. 16% of observations were of two or more animals together, while 84% were alone ($n = 118$ animals; Honess 1996b). At night *G. rondoensis* mostly uses lower strata of the forest. In Rondo F. R. mean height 3 m ($n = 156$ animals; Honess 1996b). Three young seen sharing a day nest with a Mozambique Dwarf Galago *Galagoides granti* (Lumsden & Masters 2001).

Galagoides rondoensis has an extensive vocal repertoire with at least four discrete loud-calls. These are often mixed together to form other call structures depending on the context. In Rondo F. R. 70% of calls analysed were alarm calls with only 22% species-specific advertisement calls ($n = 647$; Honess 1996b). The species-specific advertisement call is used to advertise presence and for group reassembly in the morning (Honess & Bearder 1996, Bearder *et al.* 2003, Perkin 2003, 2004).

Infants carried in mother's mouth, not clinging to her body. Mother 'parks' infant during the night but duration of parking not known (Bearder *et al.* 2003, A. Porter pers. comm.).

Reproduction and Population Structure Based on ♀♀ trapped in Pugu F. R.: antenatal body weight = 93 g ($n = 3$), postnatal lactating weight 66.5 g ($n = 2$). Trapping data suggest reproduction is seasonally bimodal. Birth periods in mid-Apr and end of Dec in Pugu/Kazimzumbwi F. R. (Perkin 2004) and Jul–Aug in Rondo F. R. This coincides with the 'short' wet season (Nov–Dec) and the 'long' wet season (Mar–May).

Predators, Parasites and Diseases Uncertain, but owls, genets *Genetta* spp., Two-spotted Palm Civets *Nandinia binotata* and snakes are likely predators. Genets and snakes invoke intense episodes of alarm calling. Alarm calls by one individual can last >40 min, whilst conspecifics situated close by remain silent until the threat has gone (A. Perkin pers. obs.). Alarm calls comprise rapid high frequency phrases of 'rapid whistles' and/or 'shivering twitters' several seconds apart linked

with ‘yaps’ (Honess 1996b). Such calls also given in presence of *G. granti*, which is known to hunt vertebrates (S. K. Bearder pers. comm.).

Unidentified yellow mites occasionally on edges of ears of mature adults in Pugu F. R. (A. Perkin pers. obs.) and orange mites on head of one individual from Rondo F. R. (Honess 1996b).

Conservation IUCN Category (2012): Critically Endangered. CITES (2012): Appendix II.

Currently listed as among the 25 most threatened primate taxa in the world (Honess *et al.* 2009). Main threat is habitat loss. Known distribution 92.6 km² of coastal forest (Pande G. R. 2.4 km², Rondo F. R. 25 km², Ziواني F. R. 7.7 km², Pugu/Kazimzumbwi F. R. 33.5 km², Litipo F. R. 4 km² and Zareninge F. R. 20 km²) (Burgess & Clarke 2000, Perkin 2004). All sites require improved management. Further surveys in potential habitat areas and research on variation among populations are priorities.

Measurements

Galagoides rondoensis

Data for two populations are presented owing to intra-population variation in vocalization and body measurements.

Galagoides orinus MOUNTAIN DWARF GALAGO

Fr. Galago uriner; Ger. Berggalago

Galagoides orinus (Lawrence & Washburn, 1936). Occas. Pap. Boston Soc. Nat. Hist. 8: 259. Bagilo, Uluguru Mts, C Tanzania.

Mountain Dwarf Galago *Galagoides orinus* adult.

Taxonomy Monotypic species. Originally described as *Galago demidovii orinus*. Recognized as a full species by Honess (1996b) and Honess & Bearder (1996) based on differences in vocalizations and morphology, and subsequently accepted by Kingdon (1997), Groves (2001) and Grubb *et al.* (2003).

Description A small, dark galago with a long-haired tail. No sexual dimorphism apparent; sexes alike in colour and pattern of pelage. Muzzle slender and slightly up-turned. Nose-stripe conspicuously white, contrasting with dark brown on either side. Eye-rings thin and dark. Ears with yellow pigmentation on anterior and outer edges; posterior dark brown. Yellow pigmentation decreases with age. Chin and neck yellowish-white. Crown, dorsum, forelimbs, thighs and flanks dark brown. Ventrums, inner-forelimbs and inner-hindlimbs creamy white. Dark yellow staining sometimes visible on chest due to glandular secretions. Lower forelimbs and lower hindlimbs yellowish-brown. Tail morphology is variable, with tails of wild-caught animals long but not densely haired, giving a bushy appearance, but Lawrence & Washburn 1936 describe tail as ‘noticeably short-haired’. Colour varies from completely reddish-brown to brown over proximal two-thirds and black over distal one-third. Penis is slightly cone-shaped, widening towards the distal end. Baculum protrudes from the end. Small, simple, spines cover the distal half and ca. 14 robust, single, pointed spines cover the proximal half, mostly on the ventral side (Perkin 2007) (spine terminology after Dixson 1995; see Anderson 2000). Species-specific advertisement call (double or triple unit scaling call), and alarm call ‘yaps’ and ‘descending

screeches' diagnostic (Honest 1996b, Perkin *et al.* 2002). Synonyms: none. Chromosome number: not known.

Geographic Variation Poorly known. Data suggest variation in vocalizations among populations in Tanzania (Udzungwa Mts, Uluguru Mts, Rubeho Mts, East Usambara Mts, Mt Rungwe) and N Malawi (Misuku Hills) (Perkin *et al.* 2002, Bearder & Karlsson 2009).

Similar Species

Galagoides zanzibaricus udzungwensis. In coastal, lowland and sub-montane forest from sea level to ca. 1070 m (Butynski *et al.* 1998). Narrowly sympatric with *G. orinus* from ca. 600–900 m at Mkungwe F. R. in the Uluguru Mts, but generally parapatric with *G. orinus* occurring at higher altitudes. About 50% larger. Overall pelage greyish-brown. Tail shorter, more thickly haired and held straight. Species-specific advertisement call a single unit 'rolling call' (Honest 1996b, Perkin *et al.* 2002). Penile morphology different (Perkin 2007).

The *Galagoides* sp. from the montane forests of the Taita Hills, SE Kenya, is similar in pelage and morphology but the species-specific advertisement call differs. Dorsal pelage cinnamon-brown with orange-brown tinge on shoulders and thighs. Tail tip appears to be bushier. It remains to be determined whether this is *G. orinus* or another taxon (Perkin *et al.* 2002).

Distribution Afromontane–Afroalpine BZ. Endemic to the montane and mid-altitude forests of most of the Eastern Arc Mts, Tanzania, southwards to Mt Rungwe in SC Tanzania, and Misuku Hills in N Malawi (Allen & Loveridge 1927, Lawrence & Washburn 1936, Honest 1996b, Butynski *et al.* 1998, Perkin 2000b, 2001, Daggart *et al.* 2006, Bearder & Karlsson 2009). Perhaps in Taita Hills, SE Kenya (Perkin *et al.* 2002).

Habitat Lives in sub-montane and montane moist forests as well as giant heather *Erica* sp. forest at the limit of the tree zone (Honest 1996b, Butynski *et al.* 1998, Perkin 2000b, 2001, 2004). It appears that disturbed forest, such as tree-fall zones, is preferred, especially areas of thick vine tangles (Perkin 2001). The canopy, mid- and understorey are utilized. Altitude range 600–2600 m (Butynski *et al.* 1998, Rovero *et al.* 2009). Mean annual rainfall 1000–>2000 mm per year (Lovett & Wasser 1993).

Abundance Abundance appears to be variable but measuring is difficult since *G. orinus* spends much time in the canopy, which probably reduces detection rates. In undisturbed forest Perkin (2001) in the Uluguru Mts, and Honest (1996b) in the East Usambara Mts report encounter rates of 2.7 animals/h ($n = 30$) and 1.2 animals/h ($n = 34$), respectively. In disturbed forest Perkin (2001) in the Uluguru Mts and Honest (1996b) in the East Usambara Mts report encounter rates of 4.5 animals/h ($n = 74$) and 4.7 animals/h ($n = 14$), respectively. Low encounter rates were also noted in the less disturbed sub-montane and montane forests of the Udzungwa (Butynski *et al.* 1998) and Rubeho Mountains (Perkin 2004). It is suspected that *G. orinus* occurs at a low density throughout much of its range (Butynski *et al.* 1998).

Adaptations Nocturnal and arboreal. Tree-holes and nests used for sleeping. One nest in the East Usambara Mts, which held three *G. orinus*, was round (ca. 30 cm diameter), and constructed of leaves and twigs 15 m up in a clump of lianas (Bearder *et al.* 2003). Locomotion mainly vertical clinging and leaping. Quadrupedal running on horizontal supports and running head first down tree trunks. Will hop to the ground but quickly returns to vertical stems. Utilizes all forest strata. Fast-moving; capable of jumps of >5 m. Utilizes a combination of hearing, sight and olfactory senses to locate prey, communicate with conspecifics and detect predators. Will mob potential predators with intense bouts of alarm calling.

Foraging and Food Omnivorous. Eats moths, cockroaches, nectar of wild bananas *Ensete edule* and gum from the liana *Toddalia asiatica*. Forages in trees and occasionally in leaf litter. Takes baits of banana and peanut butter (Perkin *et al.* 2002, Perkin 2004). In captivity accepted geckos (A. Perkin pers. obs.).

Social and Reproductive Behaviour Individuals move out of the sleeping site together at dusk but soon start to forage solitarily while maintaining contact by calling. Soon after leaving the sleeping site there is a bout of advertisement calling. There is a second calling peak at dawn (Perkin 2004). Sleeping group size ranges from 1 to 9 animals (mean 4.3, $n = 6$; Perkin 2000b, 2001, Bearder & Karlsson 2009). One tree nest hole held one mature ♂, one immature ♂, one mature ♀ and one immature ♀ (A. Perkin pers. obs.).

Reproduction and Population Structure Little known. Like other members of the genus *Galagoides*, *G. orinus* probably mouth carries infants and 'parks' them while foraging (Bearder *et al.* 2003). Reproductive parameters probably similar to those of other small, montane forest *Galagoides* spp. (e.g. Demidoff's Dwarf Galago *G. demidovii* and Thomas's Dwarf Galago *G. thomasi*).

Predators, Parasites and Diseases Unknown, but Usambara Eagle-owls *Bubo vosseleri*, genets *Genetta* spp., Two-spotted Palm Civets *Nandinia binotata*, Gentle (Sykes's) Monkeys *Cercopithecus mitis* and large snakes are likely predators. Usambara Eagle-owls, genets, African Wood Owls *Strix woodfordii* and humans may provoke intense episodes of alarm calling. Alarm calls by one individual can last for >1 hour, whilst conspecifics situated close by remain silent until the threat has gone (A. Perkin & T. Butynski pers. obs.). Of the 3–4 alarm calls known for *G. orinus* the 'yaps' and 'descending screeches' are given in situations of extreme threat from predators (Honess 1996b, Perkin 2004).

Conservation IUCN Category (2012): Near Threatened. CITES (2012): Appendix II.

Under the IUCN (2012) Degree of Threat criteria, and based on current data, *G. orinus* could be categorized as Endangered (category B,1,a,b,i,ii,iii). Conservation dependent on habitat preservation. Main threats are habitat clearance for agriculture, collection of building poles and pit-sawing. Research is required to confirm the range of this species. There is preliminary evidence of inter-population variation that may have taxonomic and conservation implications (Perkin *et al.* 2002).

Measurements

Galagoides orinus

HB: 132 (125–138) mm, n = 4

Galagoides granti MOZAMBIQUE DWARF GALAGO (GRANT'S DWARF GALAGO)

Fr. Galago du Mozambique; Ger. Mosambik-Galago

Galagoides granti (Thomas & Wroughton, 1907). Proc. Zool. Soc. Lond. 1907: 286. Coguno, Inhambane District, S Mozambique.

Mozambique Dwarf Galago *Galagoides granti* adult.

Taxonomy Monotypic species. Originally described as a full species *Galago granti* and accepted by Elliot (1913a). Subsequently, classified as *Galago senegalensis granti* (Schwarz 1931a) then, following subdivision of *G. senegalensis* and recognition of Zanzibar Dwarf Galago *G. zanzibaricus* by Kingdon (1971), classified as a southern subspecies of Zanzibar Dwarf Galago *Galago zanzibaricus granti* (Jenkins 1987) or *Galagoides zanzibaricus granti* (Olson 1979, Meester *et al.* 1986, Nash *et al.* 1989, Skinner & Smithers 1990). Placed in its current genus and confirmed at full species status by Honess (1996a, b) based on species-specific advertisement calls, and penile and hair morphology (see also Anderson, M.J. 2000, 2001, Butynski *et al.* 2006). Synonym: *mertensi*. Chromosome number: not known.

Description A small galago with a long, bushy tail and notably long, rounded, blackish ears. Gives a distinctive 'incremental call' as its vocal advertisement. This call begins quietly, increases and then decreases in volume composed of 1–17 units (mean 5.8, n = 211), each made up of an increasing number of sub-units (Honess 1996a, b). Sexes alike in colour and pattern of pelage. Forehead greyer than top of head. Pale band on the top of the snout from forehead to nostrils (inter-ocular stripe). Eye-rings black and conspicuous. Ears relatively long (>37 mm), broad, blackish behind. Dorsal surface of head, neck, back and hindlimbs drab-brown, tipped buffy-brown with slight pinkish tint. Hairs ca. 12 mm. Outside of the forelimbs drab-brown fading to white on the forefeet. Ventrums and inner surface of legs cream-buff; in some specimens upperparts of the limbs have a yellowish tinge. Ventral hairs with basal three-fifths slate-grey. Tail long and bushy, wider over distal ca. 80%, hairs dense, with hairs c. 15 mm long, soft. Tail darker

than dorsum with distal ca. 10–60% blackish-brown. Some with tail tipped white. No information available on sexual dimorphism in body size or colouration. Penis cylindrical with spines in mature ♂♂ concentrated in the mid-region. Baculum does not protrude beyond the glans (Honess 1996b, Anderson 2000, Perkin 2007).

Geographic Variation Current data suggest this species is largely consistent across its described range (Butynski *et al.* 2006). The exclusion of specimens from Newala (6) and the Uluguru Mts (3) from his analysis of *G. granti* from Mozambique suggests that Groves (2001) was not confident of their identity. However, whilst those from Newala are *G. granti* (Lumsden & Masters 2001) specimens of a similar size from the Uluguru Mts are most likely Matundu Dwarf Galago *G. z. udzungwensis* (Honess 1996b, Perkin, 2000b).

A recent field study of populations identified in Malawi as Malawi Dwarf Galago *Galagoides nyasae* (Elliot 1907) and the nearby Mount Thyolo Dwarf Galago, *Galagoides* sp. nov. 2 (Groves 2001, Grubb *et al.* 2003), suggests that they are most likely *G. granti*, based on appearance, calling patterns and habitat use (Wallace 2006). However, a population studied at Kalwe, near Nkata Bay on the western shore of L. Malawi (*Galagoides* sp. nov. 1) is more distinctive in both appearance and vocalizations and merits further study (Courtenay & Bearder 1989, Bearder & Karlsson 2009).

Similar Species Kenya Coast Dwarf Galago *Galagoides cocos*, *G. zanzibaricus* and *G. granti* replace each other from north to south in the evergreen forests of the coastal strip of eastern Africa from N Kenya (perhaps S Somalia) to extreme S Mozambique and extreme E Zimbabwe. *G. cocos* is the northern species, *G. zanzibaricus* the central species and *G. granti* the southern species (Butynski *et al.* 2006). *Galagoides granti* is parapatric with Southern Lesser Galago *Galago moholi* in Mozambique and sympatric with Rondo Dwarf Galago *Galagoides rondoensis* in STanzania.

Galagoides zanzibaricus udzungwensis. Parapatric. In Tanzania south to Kihansi and Rufiji/Kilombero River System. Ears shorter (seldom longer than 33 mm) and dusky behind. Hair of dorsum ca. 9 mm. Tail hairs of even length over tail, sparse, ca. 11 mm, wiry. Proximal ca. 75% of tail same colour as dorsum (i.e. buffy-brown); distal ca. 25% slightly darker brown or dusky. ‘Single unit rolling call’ (Honess 1996b, Butynski *et al.* 2006).

Galago moholi. Sympatric or parapatric. In savanna woodland. Pelage greyer. Tail thinner and more uniform coloured. Muzzle long (palate length: >17 mm versus <15 mm for *G. granti*; Thomas & Wroughton 1907). Two to four unit ‘bark’ advertisement call (Bearder *et al.* 1995).

Galagoides rondoensis. Sympatric in SETanzania. Small (ca. 60–70 g). Tail curled ‘bottle-brush’. ‘Double unit rolling call’ (Honess 1996a).

Distribution Endemic to Tanzania, Malawi, Zimbabwe and Mozambique. Zambeian Woodland and Coastal Forest Mosaic BZs. From Kilombero-Rufiji R., SE Tanzania, west to Udzungwa Mts and Mahale Mts (D. Moyer pers. comm.), south to the Limpopo R., S Mozambique and inland to S Malawi and extreme E Zimbabwe (Smithers & Lobão Tello 1976, Smithers 1983, Jenkins 1987, Honess 1996b, Kingdon 1997, Perkin 2000b, Butynski *et al.* 2006, Bearder & Karlsson 2009).

Galagoides granti

Habitat Inhabits natural, lowland evergreen and semi-evergreen forest, dry coastal forest, thicket and scrub (Thomas & Wroughton 1907, Smithers & Tello 1976, Honess 1996b, Lumsden & Masters 2001), as well as mist-fed evergreen forest on Rondo Plateau and dry semi-evergreen thicket on the Makonde Plateau, E Tanzania (Honess 1996b). An isolated population exists in Nambiga F. R., E Tanzania (08° 21' S, 36° 18' E), in ground-water-dependent lowland evergreen forest (Honess 1996b, Perkin 2000a). Evergreen forest (e.g. on Rondo Plateau) is uncommon throughout the range but coastal thicket is more widespread. Also in forest-cultivation.

Mean annual rainfall: 950 mm (Newala, Tanzania: Lumsden & Masters 2001) to 1100 mm (Rondo Plateau; Eriksen *et al.* 1994, Burgess & Clarke 2000). Temperature: 22–28 °C (Newala; Lumsden & Masters 2001), 11–32 °C (Rondo Plateau; Clarke 1995). Altitude: from near sea level (Ziwani) to 870 m (Rondo F. R.) (Honess 1996b, Honess & Bearder 1996) to, rarely, 1600 m (Lulanda; A. Perkin pers. comm.). In Mozambique up to 360 m (Smithers 1983).

Abundance Well distributed in evergreen and semi-evergreen forest and thicket of coastal areas of its range. Optimal habitat remains unclear. Encounters per hour for five sites were 3.8 (Rondo), 4.5 (Mtopwa), 4.5 (Noto), 4.9 (Namatimbili) and 1.2 (Lulanda) (Honess 1996, Rovero *et al.* 2009).

Adaptations Nocturnal and arboreal. An agile jumper, leaping between vertical supports, also uses quadrupedal climbing and walking or scurrying. Large independently mobile ears used in prey location. Observed urine-washing (Mtopwa: Honess 1996b). Choice of daytime sleeping sites likely to vary depending on availability. At Rondo F. R. and in type locality, tree-holes used (Thomas & Wroughton 1907, Honess 1996b, Bearder *et al.* 2003), which may be as high as 5.5 m. At Newala, associated with green, leafy nests (ca. 35 cm diameter) at ca. 3 m from the ground and possibly those made of liana fibre, leaves and twigs. Nests shared with as many as five conspecifics of mixed sex (Honess

Mozambique Dwarf Galago *Galagoides granti*.

1996b, Lumsden & Masters 2001), other galago species (*G. rondoensis*; Lumsden & Masters 2001), and even phased sharing with diurnal squirrels – indicating scarcity of nest-holes (Rondo; Honess 1996b).

Foraging and Food Omnivorous. *Galagoides granti* prefers denser parts of the understorey at 6–20 m. At Rondo, takes insects and fruits (Honess 1996b). Specimens collected at Newala had stomachs containing fruit, flower and insect remains (Lumsden & Masters 2001). In E Zimbabwe they were a persistent nuisance when small birds were being netted in the forest in the early evening, as several individuals congregated at the mist-nets to chew the heads off netted birds (Smithers 1983). Seen feeding, in a head-down position, on gum from a tree.

Social and Reproductive Behaviour Non-gregarious, except at sleeping sites. Up to six individuals may be in close proximity, but >90% of observations at night ($n = 130$) are solitary animals (Honess 1996b). The incremental call accounts for 78% of loud calls ($n = 773$). This call is often answered by conspecifics and is most frequently given in the first two hours after sunset and last two hours before sunrise; corresponding with emergence from, and gathering for, sleeping. A wide range of different calls are given, alone and in mixed sequences, indicating the importance of vocal communication (Honess 1996b). These include primary alarm calls such as the ‘buzz’ (‘single drawn out, fading unit’), ‘sweep-screech’ (‘single unit resembles a shorter, more intense buzz’), ‘screech’ (‘harsh, intense single unit, often given in a series’), ‘descending screech’ (‘series of screeches descending in volume and intensity’), ‘yap’ (‘short, dog-like, single unit, often given in series’) and ‘screech-grunt’ (‘as screech but followed by a quiet grunt that is often only audible at close range’) (Honess 1996b).

Reproduction and Population Structure Female with two foetuses recorded in Dec in southern Africa. Likely that young are

born during the warm wet summer months (Nov–Feb). Whether ♀♀ produce more than one litter per year is not known.

Predators, Parasites and Diseases Predators unknown but probably include larger snakes, owls, genets *Genetta* spp. and Two-spotted Palm Civets *Nandinia binotata*. Sometimes eaten by humans (Thomas & Wroughton 1907). Trombiculids recorded on the ear tragus (W. H. R. Lumsden in litt.). Thought, along with other galagos in East Africa, to act as an intermediate host for Yellow Fever (Haddow & Ellis 1964).

Conservation IUCN Category (2012): Least Concern. CITES (2012): Appendix II.

Higher population densities in mildly disturbed habitats and agriculture mosaics suggests no imminent extinction threat, locally or regionally. Remains vulnerable to extensive habitat reduction to meet fuel and agricultural demands of expanding human populations.

Galagoides cocos KENYA COAST DWARF GALAGO (DIANI DWARF GALAGO)

Fr. Galago de Diani; Ger. Diani-Galago

Galagoides cocos (Heller, 1912). Smith. Misc. Col. 60: 1. Mazeras, Kenya.Kenya Coast Dwarf Galago *Galagoides cocos*.*Galagoides cocos*

45° angle from the vertical plane rather than upright. Dorsum buffy-brown. Chin, chest and ventrum greyish-white, but strong yellow or orange wash may be present due to plant stains obtained while scent-rubbing (De Jong & Butynski 2011). Tail same colour as dorsum with distal one-third dark buffy-brown in some. Penis with pinnate, robust spines over most of length. Penis enlarges slightly in middle (where largest spines are located) before tapering off to the tip. Glans penis does not protrude from baculum (Perkin 2007). Immatures like adults, but white nose-stripe often incomplete towards rhinarium and penile spines absent or small.

Taxonomy Monotypic species. The Kenya Coast Dwarf Galago was originally named *Galago moholi cocos*, then elevated to *Galago cocos*, then, for many years, considered a subspecies or synonym of the Zanzibar Dwarf Galago *Galago zanzibaricus*. On the basis of its distinct loud advertising call, penile morphology and facial markings, *G. cocos* recently revived as a species (Grubb *et al.* 2003, Butynski *et al.* 2006, Perkin 2007). As such, most literature dealing with the ecology and behaviour of the Kenya Coast Dwarf Galago prior to 2003 is under the name '*Galago zanzibaricus*' (e.g. Harcourt 1986a, Harcourt & Nash 1986a, b, Nash *et al.* 1989, Bearder *et al.* 1995). Synonyms: none. Chromosome number: not known.

Description Small, brown galago with distinctive 'incremental' advertising call. Sexes similar in size and colour. Muzzle long, pointed, with broad white streak continuing well above eyes. Eye-rings prominent, formed by dark skin that continues down sides of muzzle to form 'tear' marks at the base of the muzzle. Ears large, held ca.

Geographic Variation None recorded.

Similar Species

Galagoides zanzibaricus udzungwensis. Probably sympatric, or at least parapatric, in northern part of range in NE Tanzania (Butynski *et al.* 2006). Single unit 'rolling' advertising call distinctive (Bearder *et al.* 1995). Nose-stripe greyish-white, less well defined. Patch on either side of muzzle less dark and prominent. Ears more erect, shorter. Tail short, evenly haired. In coastal and lowland forests of E Tanzania (Butynski *et al.* 2006).

Galago senegalensis. Marginally sympatric (e.g. lower Tana R.). Larger (ca. 200 g). Loud 'woo' (or 'honk') advertising call distinctive. Dorsum grey or brownish-grey. Tail grey to brown, bushier towards distal end. In woodland and acacia bushland (Butynski & De Jong 2004, Butynski *et al.* 2006, De Jong & Butynski 2011).

Galago gallarum. Probably marginally sympatric in southern part of range. Larger (ca. 200 g). 'Trumpeting quack' advertising call

distinctive. Ears black front and back. Tail grey proximally, dark brown and longer haired distally. In *Acacia–Commiphora* bushland (Butynski & De Jong 2004, Butynski *et al.* 2006).

Distribution Endemic to coastal strip of Kenya and NE Tanzania. Perhaps in SE Somalia. Northern limit perhaps Juba R. or Shabeelle R., south coast of Somalia. Confirmed northern, eastern and inland limits presented in De Jong & Butynski (2011). Southwards through coastal Kenya, to Mgambo F. R. and Kilulu Hill F. R., extreme NE Tanzania. Largely confined to the coastal strip and gallery forests (e.g. those of the lower Tana R.) from 0 to 210 m, but there is one record for Nairobi at ca. 1850 m (Butynski *et al.* 2006), but this requires confirmation.

Habitat Dry, mixed, coastal forests and thickets, and flood-plain forests. Coastal Forest Mosaic BZ. Where *G. cocos* has been most studied (i.e. at Gedi and Diani Forests, Kenya) there is a fairly thick understorey, commonly including *Lecaniodiscus fraxinifolius*, *Fagara chalybea* and *Meyna tetraphylla* at Gede, and *Diospyros abyssinica*, *Grewia goetzeana*, *Lantana camara* and *Zizyphus mucronata* at Diani. Canopy in both areas at 15–20 m, dominated by *Combretum schumannii*, while others, including *Ficus* spp. and *Tamarindus indica*, are also common. Emergents reach to 25 m (e.g. *Adansonia digitata*, *Sterculia appendiculata* and *Lannea stuhlmannii*). Rainfall bimodal, with long rains Apr–Jun and short rains in Oct–Nov. Mean annual rainfall ca. 1040 mm (Harcourt & Nash 1986b). In acacia woodland where *G. senegalensis* is absent, such as north-east of Bodhei on the north coast of Kenya (De Jong & Butynski 2011).

Abundance Variable, about 170–180 ind/km² at Gedi and Diani, but at much lower densities at some sites (Harcourt & Nash 1986a).

Adaptations Nocturnal and arboreal. Spends day in tree hollows either alone or, more often, in groups of one adult ♂, one or two ♀♀ and their offspring (Harcourt & Nash 1986a, Bearder *et al.* 2003). Sleeping site use varies. In Diani a ♂ watched at dusk used 29 sites (n = 82), while one in Gedi used only seven sites (n = 96). Sleeping in groups may help thermoregulation in this small species, though temperatures do not drop below ca. 24 °C during the day. This is probably also a predator avoidance strategy (Harcourt & Nash 1986a, b). Insect prey is located by hearing and vision. Communication is through calling and, probably, olfaction.

Foraging and Food Omnivorous. Forages only at night, most frequently alone, and usually <5 m of the ground. Occasionally comes to the ground. Forages while moving on small branches (<5 cm diameter). Moves quadrupedally both in trees and on the ground. Jumps between supports, landing front feet first or quadrupedally. Mean distance travelled per night similar between ♀♀ (1708 m) and ♂♂ (1769 m) (Harcourt & Nash 1986b). Uses mouth and hands to catch insects. Based on analysis of faecal samples (n = 258), diet is ca. 70% invertebrates and ca. 30% fruit. Fruits eaten include *L. stuhlmanni*, *Monanthotaxis fornicata*, *Uvaria acuminata*, *Grewia* spp., *Phyllanthus* sp. and *Ficus* spp. The most frequently eaten invertebrates are beetles, orthopterans and centipedes, while spiders, ants, termites, caterpillars, millipedes and true bugs are also eaten (Harcourt & Nash 1986b). Passerine feathers found in a

faecal sample in Diani suggest that small birds are sometimes eaten (Harcourt 1984). Not observed eating gum naturally in the wild (Harcourt & Bearder 1989), but will eat gum when provisioned (Nash 1989).

Social and Reproductive Behaviour Social. Unlike other galagos studied to date, adult ♂♂ consistently sleep with the same one or two adult ♀♀ and their offspring. Night-time ranges of adult ♂♂ closely coincide with ranges of those adult ♀♀ with which they sleep. Home-ranges of adult ♂♂ overlap slightly (see Figure 1 in Harcourt & Nash 1986a) with those of neighbouring ♂♂. When adult ♂ leaves his territory (which happens rarely), increased calling and chases occur (Harcourt & Nash 1986a). At Gedi there is some indication that two classes of adult ♂♂ exist (dominants and subordinates) in the population as has been reported for Southern Lesser Galago *Galago moholi* (Bearder & Martin 1979). Same-age ♀♀ usually occupy almost exclusive home-ranges, but in some cases there is considerable overlap of ranges of two ♀♀. Females with overlapping ranges regularly sleep together and are probably related. Mean home-range size is 3.4 ha (1.8–5.1, n = 6) for adult ♂♂ and 1.9 ha (1.3–2.6, n = 8) for adult ♀♀. Young ♀♀ generally remain in their natal range, while ♂♂ disperse (Harcourt & Nash 1986a). Females leave their sleeping groups and sleep alone just before they give birth and for a few weeks afterwards (Harcourt 1986a). Infant carried in mother's mouth and 'parked' on a branch while she forages.

'Incremental' advertising call often, but not always, starts with a series of high-pitched, rapidly uttered, 'chirrup' followed by units arranged in phrases that are high in frequency and amplitude, and gradually become lower in amplitude. The number of units within each phrase typically increases 'incrementally'; often, phrases with same number of units are repeated. This call has a fundamental frequency of 0.8–1.2 kHz, with harmonic spectra visible up to the tenth or eleventh harmonic at 9.3 kHz, frequency range 0.65–11.15 kHz, range of unit frequency modulation 0.68–10.37 kHz (Courtney & Bearder 1989, Bearder *et al.* 1995, Butynski *et al.* 2006).

There is a peak of calling at the beginning and end of the night (Nash 1986, Butynski *et al.* 2006), and no sex difference in the rate of calling (Harcourt 1984). About half the calls are given in answer to a call or are answered (Harcourt 1984). A common alarm call is the 'buzz and rapid chatter'. This consists of an explosive buzz unit followed by a descending, rapid series of 15–20 units. Another alarm call, 'yaps and chirrups', consists of a series of high-pitched 'yap' units about a second or less apart interspersed with a rapid series of 'chirrup' units. *Galagoides cocos* gives contact calls at night to maintain cohesion between sleeping partners and has a morning reassembly call (Bearder *et al.* 2003).

Reproduction and Population Structure Females can give birth twice a year, with infants produced in Feb–Mar and late Aug–Oct (n = 10 at Diani) (Harcourt 1986a, Nash 1983). One ♂, born in captivity to an injured wild ♀, weighed 16.5 g at birth (Harcourt 1984, 1986a). Singletons are the rule, with occasional twins. Of 12 offspring with identified mothers at Diani, one ♀ may have had twins, giving the occurrence of multiple births as 9% (Harcourt 1986a). Infants move around independently at <1 month of age and are probably able to survive without the mother by 2 months of age

(Harcourt 1984). Females probably have their first offspring at ca. 12 months of age (Nash 1983, Harcourt & Nash 1986a). Gestation 120 days (Gucwinska & Gucwinska 1968). No data available on longevity.

Predators, Parasites and Diseases It is likely that genets *Genetta* spp., snakes, large owls *Bubo* spp. and monkeys *Cercopithecus* spp. prey on *G. cocos*, but there is no direct evidence of predation. *Galagoides cocos* gives alarm calls at genets, Puff Adders *Bitis arietans* (L. T. Nash pers. comm.) and snake skins (T. Butynski pers. comm.). No information on diseases and parasites.

Conservation IUCN Category (2012): Least Concern. CITES (2012): Appendix II.

Given the use of tangled undergrowth and its predominantly insectivorous diet, *G. cocos* does well in secondary vegetation and in areas of mixed cultivation where there are large trees (e.g. Coconut Palm *Cocos nucifera*, Mango *Mangifera indica* and Cashew Nut *Anacardium occi*) in which suitable sleeping sites can be found. Much of the forest on the coast of East Africa has been removed or greatly disturbed by logging, farming and tourism, but *G. cocos* continues to survive in such habitats – sometimes at high densities.

Measurements

Galagoides cocos

HB: 158 (142–183) mm, n = 46

T: 212 (182–230) mm, n = 38

HF: 54 (40–60) mm, n = 56

E: 31 (23–40) mm, n = 39

WT (♂♂): 150 (135–167) g, n = 36

WT (♀♀): 138 (117–172) g, n = 42

Butynski *et al.* (2006) compiled from specimens obtained at Gedi and Diani (n = 35), Mazeras (n = 8) and Arabuko-Sokoke F. R. (n = 2), Kenya, and East Usambara Mts, Tanzania (n = 1) by Hollister (1924), Harcourt & Nash (1986a) and A. Perkin (pers. obs.). No significant difference in linear body measurements for adult ♂♂ and ♀♀. As such, sexes combined. WT of adult ♂♂ and adult (non-pregnant) ♀♀ significantly different. As such, WT presented by sex (Harcourt Nash 1986a, C. S. Harcourt pers. obs., L. T. Nash pers. comm.).

GLS: 42 mm, n = 13

Several localities (Groves 2001); sexes combined

Galagoides demidovii DEMIDOFF'S DWARF GALAGO

Fr. Galago de Demidoff; Ger. Demidoff-Galago

Galagoides demidovii (G. Fischer, 1808). Comm. Soc. Phy. Med. Mosq. 1(1): 57. Senegal.

Demidoff's Dwarf Galago *Galagoides demidovii* adult.

Taxonomy Polytypic species. Often referred to as 'demidoff' (e.g. Jenkins 1987, Kingdon 1997, Groves 2001, 2005c). Grubb *et al.* (2003) argue for 'demidovii', maintaining that 'demidoff' is 'unavailable'. First placed in genus *Galago* (Fischer 1806, 1808), but Smith (1833) placed the smaller galagos in *Galagoides*. Schwarz (1931a) and some subsequent authors (Jenkins 1987, Groves 2001, 2005c) retained *Galago*, but Hill (1953), Bearder *et al.* (1995), Grubb *et al.* (2003), Masters *et al.* (2007), Oates (2011), De Jong & Butynski (2012) and others recognize *Galagoides*. Of the seven subspecies recognized by Hill (1953), two have been elevated to full species: Thomas's Dwarf Galago *Galagoides thomasi* (Elliot 1907, Olson 1979, Kingdon 1997, Groves 2001, 2005c, Grubb *et al.* 2003) and Mountain Dwarf Galago *Galagoides orinus* (Lawrence & Washburn 1936, Honess & Bearder 1996, Groves 2001, 2005c, Grubb *et al.* 2003). Five subspecies (*anomurus*, *demidovii*, *murinus*, *phasma*, *poensis*) were named based principally on pelage coloration (an often unreliable character trait in galagos) and their geographic range. Major synonyms: *anomurus*, *demidoff*, *medius*, *murinus*, *peli*, *phasma*, *poensis*, *pusillus*. Chromosome number: uncertain. Chromosome number may vary with site; 2n = 44 (Makokou, C. Gabon) and = 58 (Nigeria, Togo). This has led to the suggestion that there are at least two species within what is now referred to as *G. demidovii* (Stanyon *et al.* 1992, Groves 2001). Another possible, if not likely, explanation is that one or more of the specimens sampled was a *G. thomasi*.

Description Small, mouse-sized galago. One of Africa's two smallest primates. Phenotypic diversity high within and among populations. Adult ♀ like adult ♂, but probably slightly smaller. Limited data suggest that adult ♀ weights ca. 92% as much as adult ♂. Nose upturned with prominent white stripe. Eye-rings faint and variable. Ears relatively short. Dorsum medium to dark or reddish-brown, sometimes with greyish tones. Ventrums whitish, cream or yellowish. Tail not bushy, varies in colour: brown, reddish, dark grey or black. Species-specific loud (advertisement) call a distinctive long crescendo, which increases in volume, speed and pitch and given but once or twice per bout (Ambrose 1999).

Geographic Variation Poorly known (Hill 1953, Hill & Meester 1977, Jenkins 1987, Groves 2001). No consistent descriptions with diagnostic characters exist of subspecies. There is huge within-population variation in pelage colour and body size. Until the required detailed studies of vocalizations, behaviour, morphology and genetics are undertaken, the 'subspecies' listed here (Kingdon 1997) must be regarded as tentative and provisional (Grubb *et al.* 2003).

G. d. demidovii. Senegal to Niger R.

G. d. murinus. Niger R. to Congo R.

G. d. poensis. Endemic to Bioko I.

G. d. anomurus. Right bank of Congo R into Uganda.

G. d. phasma. Congo Basin, left bank of Congo R.

Similar Species

Galagoides thomasi. Broadly sympatric. Usually >5 m or more above the ground, often in the forest canopy. Runs and leaps on medium and large branches whereas *G. demidovii* scurries. Much more common in primary and old secondary forest. Crescendo call shorter and usually given at least three times per bout. Longer nose, longer ears (24 mm vs. 20 mm for *G. demidovii*). Pelage paler, longer and looser, with less contrast between dorsum and ventrum.

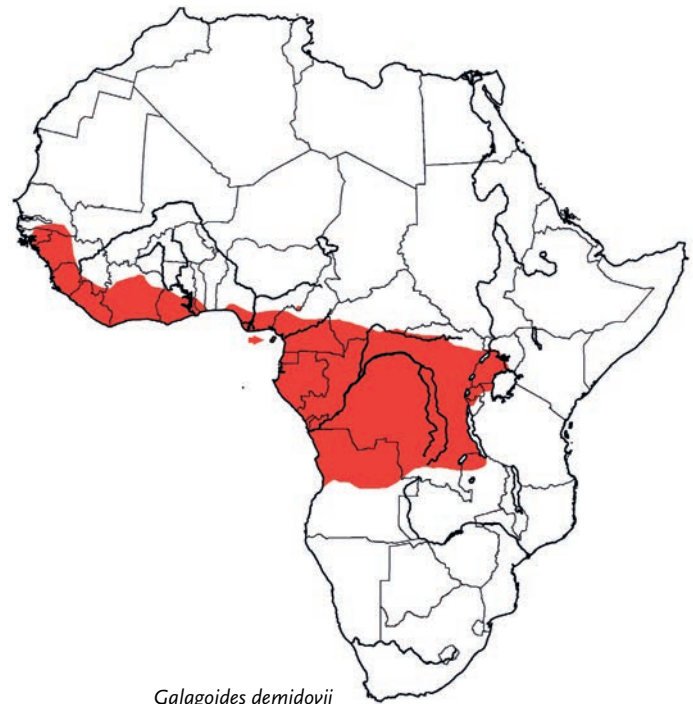

Galago matschiei. Sympatric in Uganda, probably also in E DR Congo. Much larger (200 g). Face mask well-demarcated. Ventrums pale grey. Tail dark grey. Ears more prominent. Nails keeled and pointed. Lacks 'crescendo' and 'buzz' loud calls. 'Churr' loud call repeated in sequences.

Distribution Rainforest and Afromontane–Afroalpine BZs. Endemic to the tropical forests of Africa from S Senegal southwards to Cameroon, Bioko I. and Rio Muni (Equatorial Guinea), Gabon, DR Congo and Angola, eastwards to L. Tanganyika, E DR Congo, Minziro Forest on west edge of L. Victoria, NW Tanzania, and Nile R., SE Uganda (Jenkins 1987, Nash *et al.* 1989, Kingdon 1997, Groves 2001, Ambrose 1999, 2006, Perkin & Bearder 2004).

Habitat Broad range of forest types, including evergreen, deciduous, semi-deciduous, littoral, gallery, marsh and riverine. Found along river banks, tree-fall zones, logged forest, roadsides and cultivated areas. Appears to prefer lowland secondary forest (Ambrose 1999). Present from sea level to >2000 m on Bioko I. (T. Butynski pers. obs.) and to >2000 m on Itombwe Massif, E DR Congo (Omari *et al.* 1999). Occupies fine-branch niche (± 1 cm diameter) in low, dense, secondary growth (Ambrose 1999). On Bioko I., at Moka, present within pure stands of Elephant Grass *Pennisetum purpureum*,

Lateral, palatal and dorsal views of skull of Demidoff's Dwarf Galago *Galagoides demidovii* adult.

Galagoides demidovii

>10 m from edge of montane forest at 1400 m, and sometimes common in mix of *P. purpureum*, Bracken Fern *Pteridium aquilinum*, *Harungana madagascariensis*, *Trema orientalis* and *Macaranga occidentalis* (T. Butynski pers. obs.). Of 18 encounters with *G. demidovii* at Moka, 39% in Elephant Grass, 33% in Bracken Fern, 28% in secondary forest and none in primary forest (Croce 2009). On Bioko I., present where mean annual rainfall is 2000–10,000 mm (T. Butynski pers.

obs.). At Makokou, C. Gabon (500 m asl), mean annual rainfall ca. 1700 mm, monthly mean minimum temperature is ca. 21–24 °C and monthly mean maximum temperature is ca. 26–30 °C (Charles-Dominique 1977). *Galagoides demidovii* present at 400 m asl on north bank of Congo R. at Lokutu, NC DR Congo, where mean annual temperature ca. 25 °C, no monthly mean temperature <18 °C, and annual rainfall is 1400–2200 mm (Butynski & McCullough 2007).

Abundance Often common in heavily disturbed habitats and on edge of forest. At Moka, Bioko I., *G. demidovii* encountered at 0.4 ind/h (Ambrose & Perkin 2000). Another study at Moka encountered 0.6 ind/h and 0.6 ind/km (Croce 2009). Other encounter rates are 1.3 ind/h in Taï N. P., Côte d'Ivoire; 0.2 ind/h on Mt Cameroon (Ambrose 1999); 1.6 ind/h in Korup N. P., Cameroon (Bearder & Honess 1992); 0.9 ind/h in Okomu N. P., Nigeria (Bearder & Oates 2009b). Ambrose (2002, 2006) obtained the following encounter and crescendo loud-call rates for *G. demidovii* from three sites across Uganda:

Mabira F. R., SC Uganda: 0.57 ind/h and 0.26 calls/h.

Mpanga F. R., SC Uganda: 0.16 ind/h. No calls heard.

Buhoma, Bwindi N. P., extreme SW Uganda: 0.33 ind/h and 0.20 calls/h.

Adaptations Nocturnal and arboreal. Rapid, darting (i.e. scurrying) movements on fine to medium-sized branches (± 1 cm diameter), usually below 5 m in dense secondary growth. Initiates leaps with hindlimbs, lands with forelimbs. Oval-shaped, ca. 25 cm diameter nests of leaves or bark constructed for breeding, especially in the wet season (Bearder & Honess 1992, Bearder *et al.* 2003). Nests placed <5 m above ground in very dense vegetation. Not known to use nest holes. Mother carries young in her mouth.

Foraging and Food Omnivorous. Insects chased and grabbed with one or both hands. Able to hang bipedally when foraging or feeding. Fruit picked by mouth or hand. At Makokou, diet mainly invertebrates (mainly beetles, moths and caterpillars) with some fruit, gum, leaves and buds (Charles-Dominique 1977). At Moka, often on the ground or <0.5 m above the ground, especially when foraging in Bracken Fern and Elephant Grass (T. Butynski pers. obs.). At Moka, mean height above ground 1.5 m (0–4 m, n = 18; Croce 2009), although forages to >12 m (Ambrose & Perkin 2000).

Social and Reproductive Behaviour Non-gregarious. Females have overlapping home-ranges of 0.8 ha in Gabon. Home-range of dominant ♂♂ vary 0.5–2.7 ha, usually overlap with several ♀♀. Smaller ♂♂ tolerated within range of dominant ♂ while peripheral ♂♂ occupy marginal ranges. Males leave natal area at puberty. Sleeps in groups of 2–10, huddled in dense vegetation or aggregates of leaf nests. Nest occupants usually ♀♀ with offspring, occasionally adult ♂ present (Charles-Dominique 1977). Loud (advertisement) call; long 'crescendos', which increase in volume, speed and pitch, given once or twice per bout. Used as contact, spacing and gathering call. 'Chips' produced in short phrases in the

context of mild alarm. Explosive 'buzz' for contact avoidance. 'Chips' that speed and slow are given when highly alarmed (Ambrose 1999).

Reproduction and Population Structure Females give birth once a year, usually to singleton, occasionally twins. Gestation 110–114 days. Weaned at two months, sexually mature at six months. Primary breeding season varies by region. Births C Gabon throughout the year, birth peak Jan–Apr, when fruit and insects are most abundant (Charles-Dominique 1977). Birth peaks DR Congo Sep–Oct and Jan–Feb (Vincent 1969). Infants and juveniles observed in S Cameroon in Jun, in S Gabon in Jul (Ambrose 1999). Longevity >12 years in captivity (Charles-Dominique 1977).

Predators, Parasites and Diseases Poorly known, however, likely large owls *Bubo* spp., genets *Genetta* spp., linsangs *Poiana* spp., mongooses, Two-spotted Palm Civets *Nandinia binotata* and snakes. Blood parasites in Cameroon include malarial *Plasmodium falciparum*, filarial worm *Mansonella perstans* and *Leishmania major*, although no pathological symptoms observed (E. Pimley pers. comm.).

Conservation IUCN Category (2012): Least Concern. CITES (2012): Appendix II.

Widespread across West and central Africa and patchily common. Thrives in disturbed forests and able to occupy areas affected by human activity (Charles-Dominique 1977, Ambrose 2006). If *G. d. poensis* is a valid subspecies, and endemic to Bioko I., then its extent of occurrence is <1500 km² (T. Butynski pers. obs.).

Lesley Ambrose & Thomas M. Butynski

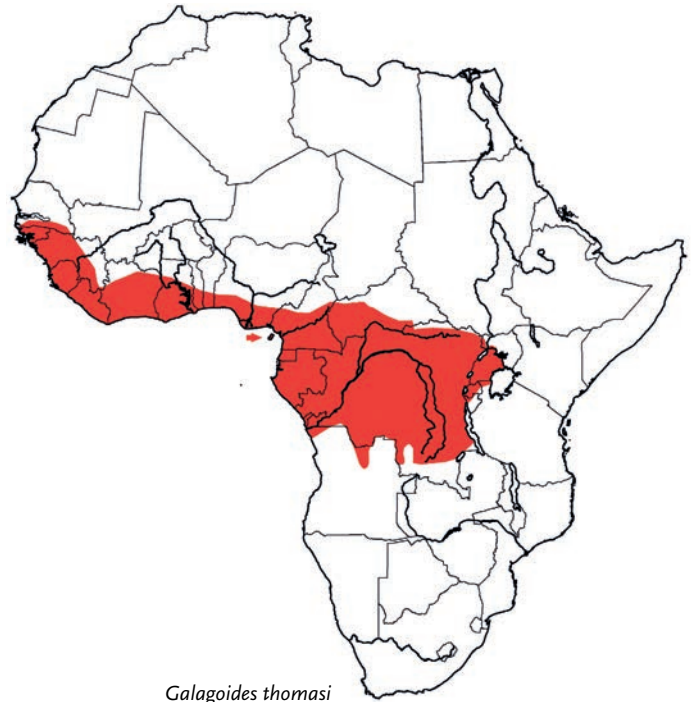

Galagoides thomasi THOMAS'S DWARF GALAGO

Fr. Galago de Thomas; Ger. Thomas-Galago

Galagoides thomasi (Elliot, 1907). Ann. Mag. Nat. Hist., ser. 7, 20: 189. Beni, DR Congo.Thomas's Dwarf Galago *Galagoides thomasi* adult.

Taxonomy Monotypic species. Elliot (1907) described Thomas's Dwarf Galago as a species, but subsequently this taxon regarded as a subspecies of Demidoff's Dwarf Galago *Galagoides demidovii*. Hill (1953) remarked that *G. d. thomasi* was a distinctive subspecies due to its larger body size and longer, looser fur. Olson (1979) resurrected *thomasi* to full species based on its morphology and sympatry with *G. demidovii*. Synonyms: none. Chromosome number: not known. Chromosome research on some specimens identified as *G. demidovii* may have, in fact, been on *G. thomasi*. This might account for the discrepancy in chromosome (2n) numbers (i.e. 44 vs. 58) reported for *G. demidovii* (Stanyon *et al.* 1992, Romagno 2001).

Description Small (ca. 100 g) galago usually found between 12–20 m in forest canopy. Diagnostic short 'crescendo' loud-call that rapidly increases in speed and pitch, usually repeated at least three times and often in sequences lasting several minutes. Muzzle comparatively long, often with a pale nose-stripe. Sexes similar in colour and pattern of pelage. Eye-rings variable; in some populations fine and indistinct, in others broad, forming a dark mask. Pale nose-stripe not sharply demarcated from the dark forehead and muzzle (as in *G. demidovii*). Dorsum dark to light brown. Ventrums slightly lighter

*Galagoides thomasi*

brown than dorsum in many populations. Pelage colour, however, strongly influenced by moult, being more ashy just before moult and darker just after. Outer limbs, hands and feet similar to dorsum. Tail long, not bushy, same colour as dorsum or slightly darker brown. Pelage overall darker, longer and looser than *G. demidovii*.

Geographic Variation Exceptionally uniform phenotypically, behaviourally and vocally. This is as expected for a relatively abundant species with an apparently continuous gene-pool. Ventrums orange in Cameroon, yellowish in DR Congo.

Similar Species

Galagoides demidovii. Broadly sympatric. Prefers undergrowth <5 m, often in secondary growth and on forest edge. Scurries on fine branches (usually <1 cm diameter). 'Crescendo' call longer and usually given but once or twice per bout. Nose pointed and upturned. Ventrums white, cream or yellow. Pelage darker, shorter and less loose, with more contrast in colour between dorsum and ventrum. Penile morphology diagnostic (Wickings *et al.* 1998).

Galago matschiei. Sympatric in Uganda, and probably also in DR Congo. Much larger (200 g). Face mask well-demarcated. Ventrums pale grey. Tail dark grey. Ears more prominent. Nails keeled and pointed. Lacks 'crescendo' and 'buzz' loud calls. 'Churr' loud call repeated in sequences.

Distribution Endemic to central Africa and West Africa. Rainforest and Afromontane–Afroalpine BZs. Distribution limits uncertain, but most likely through West Africa from Nigeria to

Thomas's Dwarf Galago *Galagoides thomasi*.

at least Côte d'Ivoire (Ambrose 1999), and perhaps as far west as Senegal (Burnham & Navaza-Leon 1998). Bioko I., Equatorial Guinea (Ambrose & Perkin 2000). From Cameroon and Gabon, southwards to N Angola and N Zambia, eastwards to L. Tanganyika, E DR Congo, Minziro Forest on west edge of L. Victoria, NW Tanzania, and Nile R., SE Uganda (Nash *et al.* 1989, Kingdon 1997, Ambrose 1999, 2006, Perkin & Bearder 2004).

Habitat Primary and secondary lowland to montane forest: evergreen, deciduous, semi-deciduous, littoral, gallery, marsh and riverine forests. Occupies plantations and farms. Prefers primary montane forest but can occur anywhere where sufficient trees remain. *Galagoides thomasi* at Moka, Bioko I., appears to differ from *G. demidovii* in that it has yet to be found in Bracken Fern *Pteridium aquilinum* or Elephant Grass *Pennisetum purpureum* (T. Butynski pers. obs.). Lower altitudinal limit poorly known, but to at least 400 m at Makokou (Charles-Dominique 1977, Ambrose 1999). Occurs >2000 m on Mt Cameroon, W Cameroon (Ambrose 1999), Pico Basile N. P., Bioko I. (T. Butynski pers. obs.) and Itombwe Massif, E DR Congo (Omari *et al.* 1999). To >2350 m in Bwindi Impenetrable N. P., SW Uganda (T. Butynski pers. obs.), and to >2690 m on Mt Tshiaberimu, E DR Congo (Sarmiento & Butynski 1997). Mean annual rainfall over geographic range from ca. 1500 to >4000 mm (T. Butynski pers. obs.).

Lateral view of skull of Thomas's Dwarf Galago *Galagoides thomasi* adult.

Abundance Locally common but patchy in distribution. Reaches highest density in montane forest and old (tall) secondary forest. Density estimates absent. At Moka, Bioko I., encountered at rate of 0.2 animals/h ($n = 9$; Ambrose & Perkin 2000). Another study at Moka encountered 0.3 animals/h and 0.3 animals/km of transect ($n = 13$; Croce 2009). Other encounter rates are 1.9 ind/km in Korup N. P., Cameroon (Bearder & Honess 1992) and 3.0 ind/h in Okomu N. P., Nigeria (Bearder & Oates 2009b).

Ambrose (2002, 2006) recorded the following encounter and crescendo loud-call rates for *G. thomasi* for seven sites across Uganda from the left bank of the Nile R. to near the border with DR Congo (range 0.10–2.00 ind/h; 0.00–1.33 calls/h):

Mabira F. R., SC Uganda: 0.42 ind/h ($n = 19$) and 0.13 calls/h ($n = 6$).

Mpanga F. R., SC Uganda: 0.46 ind/h ($n = 14$) and 0.23 calls/h ($n = 7$).

Rubongo, Murchison Falls N. P., CW Uganda: 2.00 ind/h ($n = 5$) and 0.80 calls/h ($n = 2$).

Pabidi, Budongo F. R., CW Uganda: 2.00 ind/h ($n = 3$) and 1.33 calls/h ($n = 2$).

Buhoma, Bwindi N. P., extreme SW Uganda: 0.10 ind/h ($n = 5$). No calls heard.

Kanyanchu, Kibale N. P., SW Uganda: 0.66 ind/h ($n = 15$) and 0.53 calls/h ($n = 12$).

Echuya F. R., extreme SW Uganda: 0.10 ind/h ($n = 2$) and 0.05 calls/h ($n = 1$).

Adaptations Nocturnal and arboreal. In Kibale N. P., SW Uganda, *G. thomasi* emphasizes fast and slow arboreal quadrupedalism (35%) and leaping (23%) in its locomotor repertoire ($n = 263$). Vertical clinging accounts for 54% of postures ($n = 37$). Small (<5 cm circumference) supports used 76% of time ($n = 308$). Oblique supports used 49% of time, horizontal supports 28% and vertical supports 24% ($n = 251$; Off & Gebo 2005). Can make rapid movements, mainly when agitated, and will frequently ascend and descend, leaping up to 1.8 m between supports (Ambrose 1999). Like other galagos, urine-washes and marks its surroundings with anogenital and other glandular secretions. Fluctuating intensities of yellow skin secretions from the bare face, ears, hands, feet and heels have been tentatively correlated with sexual activity (Kingdon 1997). Commonly sleeps in self-made nests in Uganda. Occasionally occupies natural crevices or tree holes, which they line with fresh leaves (J. Kingdon pers. comm.).

Foraging and Food Omnivorous. Diet in Uganda contained insects (78%), gum or resin (18%), and fruit and seeds (4%). Insects

Thomas's Dwarf Galago *Galagoides thomasi*.

most frequently eaten are *Coleoptera*, *Orthoptera* and *Hymenoptera*, however there is evidence of seasonal changes in diet (Kingdon 1971). *Galagoides thomasi* fed almost exclusively on caterpillars, which were abundant during Mar–Apr. Crickets were the principal food in Dec. Forages by running rapidly and leaping on medium-size and large branches with its back legs doubled up beneath the belly (Kingdon 1971, Oates 2011). Insects caught by a pounce and rapid grab with both hands. Able to hang bipedally when catching or eating food. Where sympatric with *G. demidovii*, usually >10 m above ground and often >20 m (Ambrose 1999, Bearder & Oates 2009a, b). At Moka, mean height during one study was 10.4 m (4–18, $n = 11$; Croce 2009) and in another study all nine animals encountered were >5 m (Ambrose & Perkin 2000). Expected to use lower strata more often where *G. demidovii* is absent, such as in Kibale N. P.; lower canopy 28% of observations, mid-canopy 63% and upper canopy 9% ($n = 250$; Off & Gebo 2005).

Social and Reproductive Behaviour Mainly solitary while foraging but maintains occasional vocal contact with conspecifics; 79% alone, 16% two individuals, 2% three individuals, 2% four individuals, 1% five individuals ($n = 142$; Ambrose 1999). Kingdon (1971, 1997) characterized this as a social species ordered into ‘clans’ of up to 12 animals in which only gravid ♀♀ separate out from their group in order to give birth in a ‘singleton nest’. Sleeps communally, with up to five individuals gathering at dawn in Cameroon (Ambrose 1999, Bearder *et al.* 2003). In Uganda, social groups of 8–12 animals occur. Even or near-even adult sex ratios and may represent adult ♂♂–♀♀ pairs supplemented by recent offspring. Adults, especially older ♂♂, frequently have wounds on face and ears. Aggression and appeasement might be partially mediated by olfactory cues emanating from skin secretions, glands and excreta. Sleeps in dense vegetation, but leaf nests are the norm in Uganda (Kingdon 1971). These nests are made at various levels in the forest strata and are either augmented with new leaves or made afresh each day. Nests made in the wet season are often lodged in tree forks, larger, and used longer compared to dry season nests (Kingdon 1997). In Kibale N. P., Uganda, nests sometimes constructed inside old nests of Robust Chimpanzees *Pan troglodytes* (Llorente *et al.* 2003).

Vocal repertoire distinct. Contact calls are short ‘crescendos’, which rapidly increase in speed and pitch, usually repeated at least three times in quick succession and often occur in sequences lasting several minutes. ‘Trills’ are associated with conspecifics meeting at dawn and can be characterized as assembly calls. Rapid, loud ‘chips’ are given in the context of mild alarm, usually in long sequences for about 30 min (Ambrose 1999). High intensity alarm calls include rapid ‘chips’ in discrete phrases. Rapid and rhythmical ‘chips’ are produced, often interspersed with ‘grunts’ and ‘buzzes’ (Ambrose 1999). Lives >10 years in captivity (Kingdon 1971).

Reproduction and Population Structure Kingdon (1971) reports a poorly defined mating peak in Uganda during Aug, and a discernible birth peak (five records) in Dec–Feb (the driest time of year). These are, however, extrapolated births and adult ♀♀ were never recorded pregnant or nursing. Nine records of subadult animals Feb–Mar support the likelihood of a birth peak Dec–Jan in Uganda. J. Kingdon (pers. comm.) observed mothers carrying infants both in their mouth (sometimes while making long jumps) and by clinging to

Thomas's Dwarf Galago *Galagoides thomasi* adult.

the mother's ventrum. At two weeks the infant is active and at three weeks makes short jumps (J. Kingdon pers. comm.). At this time infants are able to feed while hanging upside down from a branch, run along branches using four limbs, and defend themselves with open-mouth threats and bites. At four weeks the juvenile transfers urine to the hindfeet after catching it in the hands and ambitious leaps are made (Kingdon 1971). Young weaned by six weeks but continue to request and grab food from mother. J. Kingdon (pers. comm.) never saw captive mothers actively feed their young. At nine weeks the young are independent and approximately adult in size; ♀♀ fiercely repel their young at this age (Kingdon 1971). Charles-Dominique (1972) noted that the infant-to-mother relocation call transmutes into the dawn adult call that aids regrouping. Although the study in which his observations were made did not discriminate between *G. thomasi* and *G. demidovii*, it is likely that this detail concerns *G. thomasi*.

Gestation ca. 110 days (Blackwell 1969, possibly referring to what was then regarded as *G. d. thomasi*). There is an interest in the reproductive physiology of *G. thomasi* since Hill (1953) reported that the zygote uniquely implanted deep in the mucous lining of the uterus. Birth weight estimated ca. 25 g, head–body length 75 mm and tail length 90 mm (J. Kingdon pers. comm.). Birth-weights likely to depend on single or twin birth. Single young are about as frequent as twins. Sex ratios appear to be relatively consistent at 1 : 1, both at birth and among adults.

Predators, Parasites and Diseases Poorly known, however, likely to be consistent with *G. demidovii*. Genets *Genetta* spp., Two-spotted Palm Civets *Nandinia binotata*, linsangs *Poiana* spp., forest hawks and large owls *Bubo* spp. are potential predators. Small galagos preyed upon by Blue Monkeys *Cercopithecus mitis stuhlmanni* (Butynski 1982a) and Black-and-white Casqued Hornbills *Ceratogymna subcylindricus* (Kalina 1988) in Kibale Forest, SW Uganda, are probably of this species. Fraser's Eagle-owl *Bubo poensis* is broadly sympatric with both *G. thomasi* and *G. demidovii*. When *B. poensis* is detected, *G. thomasi* give long bouts of loud alarm calls (T. Butynski pers. obs.). It is likely that *B. poensis* is a major predator both of *G. thomasi* and *G. demidovii*. Because *G. thomasi* respond to the alarm calls of other galagos, as well as to their own alarm calls, there is a strong implication that this small, solitary forager is vulnerable to predation (Ambrose 1999).

Galagos, thought to be *G. thomasi*, have natural resistance to Yellow Fever virus (Bugher 1951, Simpson 1965). This discovery was of considerable medical significance because Yellow Fever is a ‘canopy

Thomas's Dwarf Galago *Galagoides thomasi* adult.

disease' that is extremely dangerous to humans, especially those living close to the forest edge. Canopy mosquito vectors probably have the opportunity to transmit this virus from galagos and monkeys to humans.

Conservation IUCN Category (2012): Least Concern. CITES (2012): Appendix II.

One of the most widely distributed and adaptable of all galagos.

Measurements

Galagoides thomasi

HB (♀): 174 mm, n = 1

T (♀): 165 mm, n = 1

HF (♀): 49 mm, n = 1

E (♀): 21 mm, n = 1

WT (♂♂): 82 (74–88) g, n = 6

WT (♀♀): 75 (60–85) g, n = 6

Centre Internationale Recherche Medicales de France (CIRMF), Franceville, Gabon (Ambrose 1999)

HB: 146 (123–166) mm, n = 47

T: 195 (150–223) mm, n = 46

HF: 52 (39–58) mm, n = 46

E: 29 (23–33) mm, n = 46

WT: 99 (55–149) g, n = 99

Numerous locations (Olson & Nash 2002); sexes combined

Glossary

abbrev. = abbreviation

adj. = adjective

cf. = *confer*, compare with; as opposed to

Lat. = Latin

pl. = plural

q.v. = *quod vide*, 'which see' (used after a word or term that appears elsewhere in the glossary)

adult: physically and reproductively mature individual.

afroalpine: habitats and/or vegetation occurring above the treeline on African mountains. Includes montane grassland, heathlands and wetlands.

afromontane: mountainous regions in Africa, e.g. afromontane forests and afromontane grasslands.

agouti: even mixture of pale- and dark-tipped hairs on the pelage, creating a grizzled, speckled or 'pepper and salt' appearance. Hairs with a specific sequence of alternating pale and dark bands creating a grizzled appearance.

Albertine Rift Valley: *see* Rift Valley (*q.v.*).

allele: alternative form of a gene. A diploid organism carries two alleles (which may be same or different) for each gene locus. At any one locus, there may be several possible alleles (although only two are present in a single organism).

allogrooming: reciprocal cleaning of the pelage.

allopatry (*adj.* **allopatric**): situation where populations of the same or different species have non-overlapping geographic ranges; refers also to populations of the same, or different, species that are geographically separated. *cf.* sympatry (*q.v.*); syntopy (*q.v.*).

anterior: of, or towards the front end of an animal.

anthropophilic: loving or thriving with humans; inhabiting domiciles; thriving in habitats substantially modified by humans (e.g. towns, farmlands).

arboreal: living mainly above the ground in trees and shrubs. *cf.* terrestrial (*q.v.*).

association: grouping of two or more species that travel and/or feed together.

auditory bulla (*pl.* **bullae**): bony structure encapsulating the middle and inner ear, situated on the ventral surface of the skull. Often greatly inflated. Sometimes referred to as tympanic bulla.

autosome: any chromosome other than the sex chromosomes.

baculum (*pl.* **bacula**, *adj.* **bacular**): os penis, or penis bone, which supports the penis in some mammals.

bicuspid: having two points or cusps (particularly of teeth).

bifid: divided by a shallow notch.

biomass: sum of the weights of the organisms in a particular area.

bipedal: body supported by the two hindlimbs; movement not using the forelimbs.

braincase (= **cranium**): that part of the skull housing the brain; the part of the skull posterior to the front line of the orbits.

buccal: cheek side of a tooth.

bushmeat: meat for human consumption derived from wild animals.

bushveld: savanna vegetation type characterized by a grassy ground layer and a moderately dense upper layer of shrubs and scattered trees.

BZ: (*abbrev.*) Biotic Zone.

C or **c**: (*abbrev.*) canine tooth; upper case denotes adult dentition, lower case denotes deciduous dentition (milk teeth). *See also* canine.

c.u.: (*Lat.* *cum unguis* = with nail) measurement of the hindfoot when length of the nail on the claw is included in the measurement. Usually hindfoot is measured without the claw because claws may be broken or worn. When length of claw is included, it is conventional to record as 'HF c.u.'. *cf.* s.u. (*q.v.*).

canine: tooth posterior to the incisors and anterior to the premolars that is usually elongated and pointed.

canopy: upper forest level, which receives the most sunlight. May be continuous or have gaps or taller emergent trees.

carnivore: animal that primarily eats flesh of other animals.

carrying capacity: maximum population size that can be sustained by the available resources in the environment.

caudal: tail; toward the tail.

cecum: saclike appendage between the small and large intestines.

central Africa: Cameroon (south of the Sanaga R.), Central African Republic (but only south of ca. 7° N), Equatorial Guinea, Gabon, DR Congo (except SE). Mainly rainforest habitats and rainforest–savanna mosaics.

cf. (in general usage): compare or compare with. In the context of descriptions, implies a difference or contrast: e.g. 'In *T. niveiventer*, ventral pelage white (cf. *T. thersites* in which the ventral pelage is dark brown).'

cf. (in taxonomy): precedes the specific name if there is uncertainty in the assignment.

cheekteeth: premolar (*q.v.*) and molar (*q.v.*) teeth combined.

cheek-pouches: pair of deep pouches extending from the cheeks into the neck skin. Used for temporary storage of food.

chromosome: one of the thread-like bodies within the nucleus of a cell, that carries the genes (genetic material) in linear order; each chromosome is composed of one long molecule of DNA (and two long molecules at cell division). Chromosomes occur in pairs (one from each parent) and are visible as rod-like bodies in cells that are dividing. The total number of chromosomes in a cell is expressed as the diploid number (2n).

cingulum (*pl.* **cingula**): ridge around the base of the crown of a tooth.

circumgenital: around the genitalia.

circumocular ring: ring around the eye.

clade: branch of a phylogenetic tree containing the set of all organisms descended from a common ancestor.

cladistic (analysis): methodology that provides a classification in which organisms are grouped in terms of the time when they had a common ancestor.

cline (*adj.* **clinal**): in context of geographic variation, a gradual

and sequential change of a character(s) without a significant break such as would justify division into subspecies or species.

comparatively: used in the context of describing the size of one character compared with the size of the same character in a different species. Sizes described as small, medium or large (if range is divided into three) or very small, small, medium, large, very large (if range is divided into five). *cf.* relatively (*q.v.*).

competitive exclusion: principle that two species cannot indefinitely occupy the same ecological niche.

condylar process: process at the posterior upper corner of the mandible, which forms the lower hinge of the jaw articulation; fits into the glenoid fossa of the skull.

condyle: rounded process on a bone, that articulates with a socket-like concavity in another bone.

congeneric: belonging to the same genus.

conspecific: belonging to the same species.

convergence: evolution of similar characteristics in unrelated animals as a result of adaptation to similar environmental conditions or for similar function.

coprophagy: eating of faeces.

copulatory plug: plug formed in the vagina of the female after copulation; formed from seminal fluids of the male. Prevents or reduces the chance of sperm from another male(s) entering the female reproductive tract if the female copulates again soon after copulation with the first male.

core area: part of the home-range that is used most intensively.

coronoid process: angular pointed process on the upper margin of the mandible, situated anteriorly to the condylar process (*q.v.*); does not participate in the jaw articulation.

corridor: broad and more or less continuous connection between adjacent land masses or habitat types that allows for dispersal of organisms between adjacent areas.

craniodental: skull and teeth.

cranium: that part of the skull housing the brain. Also called braincase.

crepuscular: at, of, twilight, when light intensity is higher than at night but lower than during the day. *cf.* diurnal (*q.v.*); nocturnal (*q.v.*).

crown: (1) top of head; (2) exposed part of a tooth (visible above gum), especially the grinding surface.

cryptic: hidden, inconspicuous, difficult to detect. Usually referring to external colouration and markings, but also behaviour.

cursorial: adapted for running.

cusp (*adj.* **cuspidate**): prominence or sharp point, such as on the occlusal surface of some teeth.

Dahomey Gap: geographic region where savanna extends southwards to the West African coast in E Ghana, Togo, Benin (formerly Dahomey) and extreme SW Nigeria. The presence of savanna forms a break (or gap) in the extensive Rainforest Biotic Zone, that extends along the West Africa coast from Sierra Leone to Cameroon. The Dahomey Gap is an important biogeographical barrier separating the faunas to the east and west of the Gap.

day-range: distance travelled during 1 day.

dental formula: simple numerical method of denoting the number of incisor (I), canine (C), premolar (P) and molar (M) teeth on one side of the upper jaw and lower jaw, and the total number of teeth. For example, the dental formula of a primitive mammal

is $I^{3/3}, C^{1/1}, P^{4/4}, M^{3/3} = 44$, which means there are three incisors, one canine, four premolars and three molars on each side of the upper jaw and also the lower jaw, making a total of 44 teeth. The formula may also be expressed in the form $^{3143}/_{3143} = 44$. Each incisor, premolar and molar is numbered according to its position in the tooth row; superscript numbers indicate upper jaw, subscript numbers indicate lower jaw (mandible), e.g. P^4 (upper fourth premolar), M_2 (lower second molar).

diagnostic: distinguishing characteristic, e.g. diagnostic features of a group of organisms.

dichromatism: condition in which members of a species show one of only two distinct colours or colour-patterns.

digit: any finger or toe.

diphyly: derivation of a taxon from two separate lines of descent. *cf.* monophyly (*q.v.*).

diploid number (2n): total number of chromosomes (including sex chromosomes) in a somatic cell of an organism.

disjunct: distinctly separate or discontinuous ranges in which one or more populations are separated from other populations by sufficient distance to prevent gene flow between them.

dispersal: one-way movement or spreading of organisms from the natal area to new areas.

display: relatively conspicuous pattern of behaviour that conveys specific information to others, usually to members of the same species; can involve visual and/or vocal elements, as in threat, courtship or greeting. A behaviour pattern that has been modified (ritualized) by evolution to transmit information by a sender to a receiver.

distal: end of any structure farthest away from the mid-line of the body or farthest from the point of attachment. *cf.* proximal (*q.v.*).

diurnal: at, active in, daytime; when light intensity is high. *cf.* crepuscular (*q.v.*); nocturnal (*q.v.*).

DNA: (*abbrev.*) deoxyribonucleic acid; the very large self-replicating molecule that carries the genetic information of a chromosome; each molecule is composed of two complementary chains of DNA.

dorsal: back or upper surface (opposite of ventral).

dorsoventral (dorsoventrally): from dorsal to ventral surface; from back to belly of an animal.

dorsum: dorsal surface of an animal.

E: length of external (outer) ear (= pinna), measured from tip of ear to the posterior point of the ear conch). Length and shape usually affected by preservation.

East Africa: Kenya, Uganda, Rwanda, Burundi and Tanzania.

eastern Africa: SE Sudan, Ethiopia, Eritrea, Djibouti, Somalia, Kenya, Uganda, Rwanda, Burundi, Tanzania, Malawi (but only south of L. Malawi and east of the Shire R. Valley) and Mozambique (but only east of Malawi and north of the Zambezi R.).

ecological niche: overall pattern of resource use by a species due to its adaptations for exploiting different resources and occupying different habitats. Role of a species in an ecological community.

ecotone: habitat created by the juxtaposition of distinctly different habitats, such as a zone of transition between woodland and grassland.

emergent trees: trees that are above the canopy.

emigration: departure of an individual from a group to live alone or join another group (usually at adulthood).

- endemic:** restricted to, peculiar to, or prevailing in, a specified country or region.
- Eocene:** geological epoch (within the Tertiary period), 38–55 mya.
- epizootic:** pertaining to disease that spreads rapidly through an animal population.
- equatorial:** geographic region bordering the equator.
- extant:** living at the present time. *cf.* extinct.
- extirpation:** extermination of a population or taxon from a given area.
- exudate:** substance that flows from the vascular system of a plant (e.g. gum, sap, resin).
- eye-ring:** ring of coloured fur around the eye.
- F. R.:** (*abbrev.*) Forest Reserve.
- family:** taxonomic division subordinate to an order and superior to a genus.
- fission-fusion social system:** social system in which individuals regularly leave for foraging (often in subgroups) but from time to time join together in larger groups.
- flank:** side of the body of a mammal.
- folivore** (*adj.* **folivorous**): animal that primarily eats leaves.
- foramen** (*pl.* **foramina**): aperture (which is usually small, round or elliptical) in a bone, or between bones, for the passage of a nerve, blood vessel or muscle.
- foramen magnum:** large opening at the posterior end of the skull through which the spinal cord passes.
- forest island:** *see* relict forest.
- frugivore** (*adj.* **frugivorous**): animal that primarily eats fruit.
- fundamental number (FN):** ambiguous term sometimes defined as (1) the total number of chromosomal arms in the full chromosomal complement of an organism (i.e. including the sex chromosomes), or (2) the total number of chromosomal arms found in the autosomal chromosomes only (i.e. excluding the sex chromosomes). When only the autosomal chromosomes are included, some authors (but not all) use aFN instead of FN to avoid ambiguity.
- G. R.:** (*abbrev.*) Game Reserve.
- gallery forest:** type of forest outlier (in a savanna region) found in narrow sheltered valleys and ravines on hillsides, where soils are moist enough, and conditions humid enough, to support rainforest trees (Rosevear 1953).
- genotype:** genetical term to describe the genetic constitution of an individual inherited from its parents. *cf.* phenotype (*q.v.*).
- genus** (*pl.* **genera**): taxonomic division superior to species and subordinate to family.
- geographical range:** area over which a population or taxon is distributed.
- gestation:** development of embryo/foetus, which takes place in the uterus; the period during which this development takes place. The gestation period is defined as the interval between conception and parturition (birth). Strictly speaking, the gestation period is not the interval between copulation (mating) and parturition (birth), although many authors take it to be this interval.
- glans penis:** bulbous tip of the penis.
- GLS:** greatest length of skull, measured from anterior end of incisor teeth or nasal bone (whichever is most anterior) to the posterior end of the skull (occiput, occipital condyles or auditory bullae, whichever is most posterior).
- gracile:** relatively slender, delicately or lightly built. *cf.* robust.
- graminivore = granivore** (*adj.* **graminivorous = grani-vorous**): an animal that primarily eats grains and seeds.
- gregarious:** living together in groups, flocks, herds. *cf.* solitary.
- Gregorian Rift Valley:** *see* Rift Valley.
- guard hair:** long thin bristle-like hairs, mainly on the back and flanks, that project beyond the soft hairs of the pelage; when present, conspicuous but never as numerous as soft hairs; probably tactile in function.
- gumivore** (*adj.* **gumivorous**): animal that primarily eats plant exudates (e.g. gum, sap, resin).
- GWS:** greatest width of skull *See also* zygomatic arch.
- hallux:** first digit of the hindlimb; the big toe.
- HB:** length of head and body, from tip of nose/snout to base of tail.
- HF:** length of hindfoot (measured from the 'ankle bone' to the tip of the longest digit; usually measured without including the claw. *See also* c.u.; s.u.).
- herbivore** (*adj.* **herbivorous**): animal that eats plants.
- high forest:** rainforest that has matured, stabilized and reached the climax stage of succession.
- highveld:** high plateaux characteristic of inland southern Africa, dominated by grasses.
- Holocene:** epoch of the Quaternary period (*q.v.*) following the Pleistocene epoch (*q.v.*), present time to ca.11,000 years ago. Sometimes referred to as the 'Recent' epoch.
- holotype:** single specimen designated or indicated as 'the type' by the author at the time of publication of the original description of a new species or subspecies. The holotype illustrates the definitive characters of that new species or subspecies. Also called 'type' (as in 'type specimen' and 'type locality').
- home-range:** area (expressed in square metres, hectares, or square kilometres) routinely used by an animal for its day-to-day activities and requirements, and which contains the resources required for survival and reproduction. Within the home-range there may be a 'core area' or 'centre of activity', that is utilized more frequently than other parts (e.g. 80% or 90% of known time-based observations). *cf.* territory (*q.v.*).
- homoplasy:** similarity between different organisms or taxa resulting from evolution along similar lines (e.g. convergent evolution) rather than descent from a common ancestor.
- hybrid:** offspring of parents of different species.
- I or i:** (*abbrev.*) incisor (*q.v.*) tooth; upper case denotes adult dentition, lower case denotes deciduous dentition (milk teeth). *See also* incisor.
- I. (pl. Is.):** (*abbrev.*) Island.
- immigration:** movement of new individuals into a population.
- inbreeding:** mating among closely related individuals.
- incertae sedis:** (*Lat.*) taxon of uncertain status and that may be taxonomically invalid.
- incisor:** tooth rooted in the premaxillary bone (most anterior bone of upper jaw) and in an equivalent position in the mandibular bone (lower jaw); always anterior to the canine teeth, if present. The number and form of the incisor teeth varies in different species.
- infanticide:** deliberate killing of infants.
- infraorbital foramen** (*pl.* **foramina**): foramen that connects the orbit (eye-socket) with the rostrum (premaxilla and maxilla bones); outer surface often expanded to form zygomatic plate (*q.v.*); foramen contains the masseter medialis muscle.

- inguinal:** groin.
- inner:** nearest to mid-line of body, e.g. inner incisor, inner margin of ear.
- insectivore** (*adj.* **insectivorous**): animal that primarily eats insects.
- inselberg:** isolated rocky hill; term used mainly in western Africa. *See also* *jebel*; *kopje*.
- insular:** isolated from others of the same type (as on an island).
- inter-aural:** between the ears.
- inter-group:** between or among groups.
- inter-ocular stripe:** stripe that runs vertically between the eyes.
- inter-orbit/inter-orbital constriction:** narrowest part of the skull between the orbits when viewed dorsally at the level of the frontal bones.
- inter-specific:** between species.
- intra-group:** within a group.
- intra-specific:** within one species; among members of the same species.
- invertebrate:** animal without a backbone (e.g. insects, spiders, worms, crustaceans).
- ischial callosities:** pads of tough, fatty, horny skin attached to the flattened parts of the ischium of all Old World monkeys.
- ischium:** one of the three bones of the pelvis.
- jebel:** isolated rocky hill in savanna and arid habitats; term used mainly in northern Africa. *See also* *inselberg*; *kopje*.
- juvenile:** individual between infancy and sexual maturity.
- Kaokoveld:** area of sandstone and lava hills of the Namib Desert (Biotic Zone 11b) in NW Namibia, inland from the Skeleton Coast.
- Karoo:** southern African term for grassy dwarf shrubland on the semi-arid central plateau of the western half of South Africa at altitudes of 500–2000 m.
- karyological:** nucleus and chromosomes.
- karyotype:** chromosomes in the cell of an animal.
- kopje:** rocky hill with boulders, rock crevices and sparse vegetation; term used mainly in southern Africa. *See also* *inselberg*; *jebel*.
- labial:** lips; situated near the lips; on the outer side of the teeth within the mouth. *cf.* *lingual* (*q.v.*).
- labially:** in the direction of the lips. *cf.* *lingually* (*q.v.*).
- lachrymal bone:** small bone in skull situated at the upper anterior margin of the orbit, near the lachrymal (tear) gland.
- lactation:** secretion of milk for nourishing the young after birth.
- lambdoid crest (= supraoccipital crest):** crest or ridge of bone running transversely across back of the skull at the junction of the dorsal (parietal) and posterior (occipital) bones of the braincase.
- lambdoid suture:** line at the junction of the occipital and parietal bones of the skull. May be clearly defined in juveniles or obscured by complete fusion in adults, or by the formation of a lambdoid crest.
- lateral:** located away from the mid-line, at or toward the sides.
- lectotype:** specimen chosen from syntypes (*q.v.*) to stand as ‘the type’ of a species or subspecies when no holotype (*q.v.*) was designated by the author who described the new species or subspecies.
- liana (= liane):** climbing woody plant (woody vine).
- limiting factor:** principle that the growth or functioning of an organism is limited when any essential factor (or resource) is lacking or in short supply, regardless of the quantity available of any other factor (or resource). The principle may also be applied to the proliferation and/or distribution of a population or species.
- lingual:** pertaining to the tongue; situated near the tongue; on the inner (tongue) side of the mouth. *cf.* *labial* (*q.v.*).
- lingually:** in the direction of the tongue. *cf.* *labially* (*q.v.*).
- longitudinal:** lengthwise; running in a head to tail direction. *cf.* *transverse* (*q.v.*).
- lowveld:** savanna at lower altitudes below the Great Escarpment of South Africa, with vegetation consisting of a grassy lower layer and a woody upper layer of shrubs and/or trees, at either high density (woodland) or intermediate density (bushveld, *q.v.*).
- M:** (*abbrev.*) molar tooth. *See also* *molars*.
- Maghreb:** *see* north-west Africa.
- mandible:** lower jaw.
- mandibular ramus:** one of the two branches (sides) of the mandible (*q.v.*); the two rami are joined at the mandibular symphysis.
- mastoid:** bone on the posterior ventral part of the skull, immediately behind the auditory meatus (auditory opening).
- matrilineal:** kinship or descent through female lines.
- maxilla** (*pl.* **maxillae**): one of the pair of bones in the skull that forms that part of each upper jaw in which the canine (*q.v.*) (if present) and cheekteeth (premolars and molars) (*q.v.*) are rooted.
- maxillary:** pertaining to the maxilla (*q.v.*).
- maxillary process:** projection of bone from the maxilla, which forms the anterior portion of the zygomatic arch (*q.v.*); usually oriented vertically to the anterior–posterior line of the skull.
- meatus:** passage or channel; the opening of a passage.
- medial:** situated in the middle.
- melanistic:** having an abnormally large amount of black or dark pigment in pelage and skin.
- metabolic water:** water produced by oxidative processes within the body; an important source of water for arid-adapted mammals when free (drinking) water and water within the food is in short supply or unavailable.
- metacarpals:** long bones of the hand, situated between the carpal bones of the wrist and the proximal phalanges of the fingers.
- metatarsals:** long bones of the foot, situated between the tarsal bones of the ankle and the most proximal phalanges of the toes.
- mid-dorsal stripe (or line):** in primates, a stripe of differentially coloured fur that runs along the ridge of the back.
- migration:** movements of species that travel, predictably and more-or-less directly, from one habitat to another (and back again), along predetermined routes, in response to seasonal changes in climate, food supply or any other resource. *cf.* *localized movements* (*q.v.*); *nomadic movements* (*q.v.*).
- milk teeth:** teeth (usually simple) occurring in newborn mammals, or appearing soon after birth, and preceding the permanent teeth of the adult animal. Also called deciduous teeth.
- Miocene:** geological epoch (within the Tertiary period), ca. 5–23 mya.
- miombo:** vernacular name applied to trees in the genus *Brachystegia*; a type of savanna woodland in the Zambezian region where *Brachystegia* spp. are the commonest trees or one of the commonest trees.
- mitochondrial DNA:** small amount of DNA contained within the mitochondria of a cell.

- molar**: grinding tooth; the most posterior teeth of the cheekteeth in adult mammals. Not preceded by deciduous (milk) teeth.
- molariform**: having approximately the form of a molar tooth.
- monogamy** (*adj.* **monogamous**): mating system in which one male mates with one female. Neither sex has the opportunity of monopolizing additional members of the opposite sex. Fitness often maximized through shared parental care (Emlen & Oring 1977). *cf.* polygyny (*q.v.*).
- monophyletic**: describes a taxonomic group descended from a common ancestor that was itself a member of that taxonomic group, and including *all* the descendants of that ancestor (Groves 2001). *cf.* paraphyletic (*q.v.*); polyphyletic (*q.v.*).
- monophyly**: derivation of taxa from a common ancestor. *cf.* diphily (*q.v.*), polyphyly (*q.v.*).
- monotocous**: normally having only one young per litter (twinning, if it occurs, is very rare and abnormal). *cf.* polytocous (*q.v.*).
- monotypy** (*adj.* **monotypic**): describes a taxon containing only one intermediately subordinate taxonomic unit, e.g. a monotypic family contains only one genus; a monotypic genus contains only one species. *cf.* polytypy (*q.v.*).
- montane**: mountain habitats.
- mopane**: vernacular name applied to the tree *Colophospermum mopane*; a type of savanna woodland in the Zambezi region in which *C. mopane* is the commonest species of tree.
- multimale group**: group of animals in which several males and several females are reproductively active.
- Mt.** (*abbrev.*) Mount.
- mtDNA**: (*abbrev.*) mitochondrial DNA (*q.v.*).
- Mts.** (*abbrev.*) Mountains.
- muzzle**: snout; the nose and jaws of a mammal.
- mya.** (*abbrev.*) million years ago.
- n. d.**: (*abbrev.*) no data.
- N. P.** (*abbrev.*) National Park.
- natal group**: group into which an individual is born.
- neonate**: newly born animal.
- neoparatype**: any specimen described at the same time as the neotype (*q.v.*).
- neotype**: specimen selected as the type in cases where the primary types are definitely known to be lost or destroyed.
- niche**: *see* 'ecological niche'.
- nipple**: external opening of a mammary gland. Nipple number and position vary according to the taxon, but are generally consistent within a species. Nipples arranged in pairs, one of the pair on each side of the body.
- nocturnal**: active mainly during the night. *cf.* crepuscular (*q.v.*); diurnal (*q.v.*).
- nomadic movements**: irregular and unpredictable movements, from one locality to another, made by species living in unpredictable habitats. *cf.* localized movements (*q.v.*); migration (*q.v.*).
- nomen dubium**: when the available evidence is not sufficient to permit the identification of a species, its name is considered to be a *nomen dubium* and, therefore, not available for taxonomic purposes.
- nomen nudum**: name that is not valid because, when it was originally published, the organism to which it referred was not adequately described, defined or sketched. The name is, therefore, invalid because it is impossible to associate it indisputably with any specific organism.
- nominate subspecies**: subspecies that bears the name of the species to which it belongs (e.g. *Cercopithecus mitis mitis*), only brought into existence by the creation of one or more other subspecies in the same species (e.g. *Cercopithecus mitis kolbi*).
- North Africa**: those parts of Mauritania, Morocco, Algeria, Tunisia, Libya and Egypt that are north of the Sahara Desert.
- north-central Africa**: Southern Chad and southern Sudan, west of the Nile R. and south of the Sahara Desert. Mainly savanna habitats.
- north-west Africa**: (= **Mahgreb**) those parts of Mauritania, Morocco, Algeria and Tunisia that are north of the Sahara Desert.
- nulliparous**: not having given birth.
- occiput**: posterior part of the skull, above the foramen magnum (*q.v.*).
- occlusal**: pertaining to the biting surface of a tooth.
- Oligocene**: geological epoch (within the Tertiary period), ca. 23–38 mya.
- omnivore** (*adj.* **omnivorous**): animal that eats a wide range of foods, including both animal and plant material.
- one-male group**: group containing several reproductively active females but only one reproductively active male.
- orbit**: bony cavity (eye-socket) in which the eye is situated.
- order**: taxonomic division subordinate to class and superior to family.
- oestrus**: period during which a female mammal will permit copulation.
- outer**: farthest from the mid-line of the body.
- P** or **p.** (*abbrev.*) premolar tooth; upper case denotes adult dentition, lower case denotes deciduous dentition (milk teeth). *See also* premolar.
- Palaearctic**: zoogeographic region comprising Europe, North Africa and Asia (except for southern portion of the Arabian Peninsula and tropical and sub-tropical regions of the Oriental Region).
- Palaeocene**: geological epoch (within the Tertiary period), 55–65 mya.
- palate**: roof of the mouth. The anterior part (hard palate) comprises the bony palate (formed by the premaxillae, maxillae and palatine bones), and a covering mucous membrane. The posterior part (soft palate) is composed only of muscular tissue covered by a mucous membrane.
- parapatry** (*adj.* **parapatric**): situation where two or more species have geographic ranges that are contiguous but do not overlap. This abutting may be along a line of habitat discontinuity, ecotone, or altitudinal/climatic contour, but may also arise from competitive exclusion of one (or both) by the other.
- paraphyletic**: describes a taxon containing units that have evolved from a single ancestral taxon but which do not contain all of the descendants of the most recent common ancestor.
- paratype**: specimen collected at the same time and place as the holotype (*q.v.*) and designated by the original authority as such. There may be one or more paratypes.
- parietal**: one of the pair of bones forming the vault of the braincase, situated between the frontal and the occipital bones.
- parous**: having given birth.

- parturition:** process of giving birth.
- pectoral:** pertaining to or situated on the chest.
- pelage:** hairy, woolly or furry covering of the body in mammals. The pelage variously consists of hairs, guard hairs and underfur according to the species.
- perineal swelling:** inflation with fluid of the tissue between anus and vulva, signalling onset of oestrus and, at its fullest, ovulation.
- phenotype:** visible characters of an individual resulting from the interaction between the genotype (*q.v.*) and the environment.
- philopatry:** tendency to remain in or consistently return to the place where one was born.
- phylogenetics:** pertaining to the line of descent of a taxon; a method of classification that attempts to show the evolutionary relatedness of organisms.
- phylogeny** (*adj.* **phylogenetic**): evolutionary history and line of descent of a species or higher taxonomic unit.
- pinna** (*pl.* **pinnae**): external (outer) ear.
- plantar:** of the sole of the foot.
- Pleistocene:** geological epoch (within the Quaternary period), ca. 10,000 to 1.7 million years ago.
- Pliocene:** geological epoch (within the Tertiary period), ca. 2–5 mya.
- polygamous:** mating system in which both males and females mate with multiple members of the opposite sex.
- polygynous:** mating system in which males mate with more than one female and females typically provide most of the parental care.
- polymorphism** (*adj.* **polymorphic**): existence, within a species or population, of individuals having different forms (colour, size, shape, etc.).
- polyphyletic:** describes a taxon derived from two or more ancestral sources; not of a single, immediate line of descent (Mayr *et al.* 1953). *cf.* monophyletic (*q.v.*).
- polyphyly:** derivation of a taxon from two or more ancestral sources. *cf.* monophyly (*q.v.*).
- polytypy** (*adj.* **polytypic**): taxon that has several taxa in the next lower taxonomic category, e.g. a polytypic family contains two or more genera, a polytypic genus has two or more species. *cf.* monotypy (*q.v.*).
- population:** all the individuals that comprise a single interbreeding group.
- posterior:** of or towards the rear of an animal.
- postorbital:** behind (posterior) to the orbit.
- premaxilla:** one of a pair of bones at the anterior end of the skull that bears the incisor teeth.
- premolar:** tooth situated immediately anterior to the molar teeth; usually preceded in time by deciduous (milk) tooth.
- preorbital:** anterior to the eye.
- primary forest:** mature, undisturbed, forest.
- primitive feature:** behavioural or morphological feature that is characteristic of a species and its ancestors.
- prognathism:** prominence of the snout.
- promiscuity:** mating system in which each male mates with several females and each female mates with several males.
- proximal:** nearest to the body or to the mid-line of the body; nearest to the point of attachment. *cf.* distal (*q.v.*).
- pterygoid:** one of a pair of cranial bones forming part of the roof of the mouth.
- quadrupedal:** body supported by four limbs; movement using all four limbs.
- Quaternary:** geological period, present time to ca. 2 mya, comprising two epochs: Pleistocene (*q.v.*) and Holocene (Recent) (*q.v.*).
- R.:** (*abbrev.*) River.
- race:** *see* subspecies.
- ramus:** one half (left or right) of the lower jaw or mandible.
- relict forest:** forest that persists where local conditions are favourable after the disappearance of forest from the surrounding area as a result of climate change or human activity. Relict forests include those at the base of inselbergs that are watered by rainwater running off the inselberg, and forests growing in graveyards and sacred sites that are protected. Sometimes known as forest islands.
- relict population:** one that persists where local conditions are favourable after the extirpation of the species from at least part of its former range.
- resident:** living within a definite, limited range, as opposed to being migratory or nomadic.
- Rift Valley:** deep valley extending from the Red Sea through Ethiopia and East Africa to Malawi; formed ca. 12 mya by subsidence of the valley floor and uplifting of the edges to form mountains and highlands. Four parts: (1) Ethiopian Rift Valley dividing the Ethiopian Plateau into two parts; (2) Albertine Rift Valley (= Western Rift Valley) in Uganda, E DR Congo and W Tanzania; (3) Gregorian Rift Valley (= Eastern Rift Valley) in N Kenya, C Kenya and N Tanzania; (4) Malawian Rift Valley – the extension of the Albertine Rift Valley in Malawi.
- riparian:** habitat along the banks of a waterway.
- riverine forest:** forest growing along the banks of a river or stream where conditions are moister than in the surrounding area.
- robust:** relatively heavily and strongly built. *cf.* gracile.
- s.u.:** (*Lat. sans unguis* = without claw) sometimes added as a suffix to the hindfoot measurement to emphasize that HF has been measured without the claw. However, since this is the standard method of measurement, most authors write ‘HF’, not ‘HF s.u.’. *cf.* c.u. (*q.v.*).
- sagittal crest:** longitudinal crest of raised bone on the mid-dorsal line of the cranium.
- saltatorial:** jumping or leaping on the two hindlimbs.
- scent gland:** odour-producing gland.
- scent-mark:** olfactory message communicated by rubbing glandular secretions or leaving urine or faeces at a specific site.
- scrotum:** external sac containing the testes and epididymides in male mammals.
- secondary compounds:** poisons produced by plants that deter animals from eating them.
- secondary forest:** forest characterized by immature stages of the succession cycle.
- sedentary:** occupying a relatively small home-range.
- sensu lato:** in a broad sense.
- sensu stricto:** in a restricted sense.
- septum:** dividing wall separating two cavities.
- sex ratio:** number of males to the number of females, usually expressed as a proportion to one male, e.g. 1 : 1 (equal numbers of males and females), 1 : 0.5 (= twice as many males as females), 1 : 2 (= twice as many females as males).

- sexual dimorphism:** observable (phenotypic) difference(s) (e.g. in colour, size or form) between the males and females of a species or higher taxon.
- sibling species:** true species, that are reproductively isolated and do not interbreed but are difficult to separate solely on basis of morphological characters.
- side-stripe:** longitudinal stripe(s) of contrasting colour on each flank, usually from shoulder to rump or upper part of hindlimbs.
- singleton:** neonate that is born singly as opposed to being one of a larger litter.
- sister species:** species that are thought to have arisen from a single dichotomous splitting event.
- solitary:** unsocial; not living in a social group. *cf.* gregarious.
- south-central Africa:** Angola, SE DR Congo, Zambia and Malawi (but only west of L. Malawi and the Shire R. Valley).
- southern Africa:** south of the Cunene R. and Zambezi R., i.e. Namibia, Botswana, Zimbabwe, southern Mozambique and South Africa (after Smithers 1983).
- species:** populations(s) of closely related and similar organisms, that are capable of interbreeding freely with one another, and cannot or typically do not interbreed with members of other species.
- species-group (= superspecies):** two or more closely related species.
- species-specific:** characters that distinguish a species (e.g. shape, colour, markings, habits).
- sternal:** chest region near the sternum (breastbone).
- sub, sub-:** prefix meaning under, signifying beneath or ventral to (as in anatomical features) or south of (as in sub-Saharan); less than (as in subsonic); not quite, nearly, almost, somewhat (as in subequal, subtriangular). In taxonomy, indicates a group just below the status of the taxa immediately following it (e.g. a genus may contain two or more subgenera).
- subadult:** individual between sexual maturity and full adulthood; not yet fully adult physically and/or socially.
- subauricular:** below the ear.
- subcaudal:** below the tail.
- subspecies (= race):** geographically localized and isolated subdivision of a species, which differs genetically, morphologically and taxonomically from other subdivisions of the species.
- subterminal:** just below the end or tip.
- suckling:** act of a mother giving milk directly from her breast (mammary glands) to her young. Mothers suckle; their young suck.
- supraoccipital crest:** ridge of bone, oriented transversely across the back of the skull, at the junction of the parietal and/or supraoccipital bones and the occipital bone. Sometimes referred to as the lambdoid crest.
- supraorbital:** above (dorsal to) the orbit.
- supraorbital ridge:** ridge of bone along upper rim of orbit (eye-socket); can be well developed, low or absent.
- sympatry** (*adj.* **sympatric**): the situation where populations of two or more different species have overlapping geographic ranges; refers also to populations of two or more species whose geographic ranges are partly or wholly overlapping. They may or may not interact. *cf.* allopatry (*q.v.*); syntopy (*q.v.*).
- synonym:** one or more different names for the same taxonomic unit. A synonym may be a 'senior synonym' (the oldest name), or a 'junior synonym' (a more recent name), that is no longer considered as valid. May be used to refer to all names that have been associated, at some time in the past, with the taxonomic unit as currently understood.
- syntopy** (*adj.* **syntopic**): describes the situation where two or more species use the same or similar habitats and activity times. They may or may not interact. *cf.* allopatry (*q.v.*); sympatry (*q.v.*).
- syntype:** any specimen, or one of a series of specimens, used to designate a species when a holotype (*q.v.*) and paratype(s) (*q.v.*) have either not been selected, or have been lost or destroyed.
- systematics:** the science of arranging organisms in a way that reflects their evolutionary relationships; such relationships may be expressed as a phylogeny (*q.v.*). Often defined (somewhat incorrectly) as a synonym of taxonomy (*q.v.*).
- T:** length of tail, measured from anterior of the first caudal vertebra to the posterior end of the last caudal vertebra (excludes tufts, bristles, etc. at tip of tail).
- tapetum:** layer of the eye (of some animals) that enhances night vision.
- taxon** (*pl.* **taxa**): any defined unit (e.g. family, genus, species, subspecies) in the classification of organisms.
- taxonomy:** science of biological nomenclature; the study of the rules, principles and practice of naming and classifying species and other taxa. Sometimes considered as an integral part (and near synonym) of systematics (*q.v.*).
- terra firma forest:** lowland forest that is not seasonally flooded.
- terrestrial:** living primarily on the ground. *cf.* arboreal (*q.v.*).
- territory:** area defended by an individual against certain other members of the species, usually by overt aggression or advertisement; territory is marked by the urine, faeces or glandular secretions of the territory's owner. *cf.* home-range.
- Tertiary:** geological period, 2–65 mya, comprising five epochs: Palaeocene, Eocene, Oligocene, Miocene and Pliocene (*q.v.*); followed by the Quaternary period (*q.v.*).
- testes:** male gonads, or testicles, in which spermatozoa are formed and in which the male hormone is produced.
- TL:** total length from tip of snout to the distal end of the tail bone (excludes tufts, bristles, etc. at tip of tail). Equivalent to the head and body length plus tail length added together. *See also* HB and T.
- topotype:** any specimen from the type locality (*q.v.*), i.e. the same locality as that from which the holotype (*q.v.*) was taken.
- topotypical:** pertaining to the type locality (e.g. a topotypical population is one found at the type locality).
- transverse:** in a direction across the body from side to side. *cf.* longitudinal (*q.v.*).
- Tropical:** geographical region between tropic of Cancer (23.5° N) and tropic of Capricorn (23.5° S).
- tympanic bulla** (*pl.* **tympanic bullae**): one of a pair of usually rounded bony capsules, on underside of skull (one on each side), housing structures of the middle and inner ear in many mammals. Also called auditory bulla (*q.v.*).
- type description:** original description of a species; the original description of the holotype (and paratype[s] if included).
- type locality:** locality from which a holotype (*q.v.*), lectotype or neotype was collected. Also called topotypical locality.
- type series:** holotype and all specimens collected at the same place and time and used, together with the holotype, to describe a new species.

type species: usually the species that was the first to be described under the name of a new genus. Not all genera had a designated type species when they were first created; in such cases, other rules determine which species will be the type species.

type specimen: *see* holotype.

underfur: dense and often woolly layer of the pelage, situated close to the skin and below the soft hairs and guard hairs.

understorey: part of a forest that lies below the canopy.

vagrant: individual that has been found well outside the normal geographic range of its species.

veld: Afrikaans word, used mainly by southern African biologists, to refer to a wide variety of grassland vegetation types typically used for grazing. *See also* bushveld, highveld, lowveld.

ventral: underside or lower surface (opposite of dorsal).

vertebra (*pl.* **vertebrae**): any of the bones that make up the backbone.

vibrissa (*pl.* **vibrissae**): long stiff hairs on the face, especially around nostrils and lips; often associated with the perception of tactile sensation; 'whiskers'.

vlei: southern African term for a marsh or swamp, either permanent or seasonal.

wadi: desert valley, usually dry at the surface except after heavy rainfall.

West Africa: ca. south of 18°N from Senegal to the Sanaga R. in Cameroon, and Bioko I. (Equatorial Guinea) (Rosevear 1965).

WT: weight (mass) of an individual.

zygomatic arch: one of a pair of cheekbones, formed of the maxillary process anteriorly, jugal bone medially and squamosal bone posteriorly. Ranges from massive, broad, widely flared and bony, to frail, slender and cartilaginous. When present, provides protection to the eyes and orbits. Also called zygoma.

zygomatic width (ZW): greatest width between the outer aspect of one zygomatic arch to the equivalent position on the opposite zygomatic arch. *See also* GWS.

| <i>Dendroprionomys rousseti</i> Velvet Climbing Mouse (Congo Tree Mouse) – C. Denys | 185 | <i>Lophiomys imhausi</i> Maned Rat (Crested Rat) – D. C. D. Happold | 214 |
| GENUS <i>Malacothrix</i> Long-eared Mouse – D. C. D. Happold | 186 | FAMILY MURIDAE Gerbils, Jirds, Rats and Mice – M. D. Carleton & G. G. Musser | 216 |
| <i>Malacothrix typica</i> Long-eared Mouse – D. C. D. Happold | 186 | SUBFAMILY DEOMYINAE Spiny Mice, Link Rat and Brush-furred Rats – M. D. Carleton & G. G. Musser | 217 |
| GENUS <i>Megadendromus</i> Bale Mouse – D. W. Yalden | 188 | GENUS <i>Acomys</i> Spiny Mice – F. Dieterlen | 217 |
| <i>Megadendromus nikolausi</i> Bale Mouse (Nikolaus's African Climbing Mouse, Giant Climbing Mouse) – D. W. Yalden | 188 | <i>Acomys airensis</i> Air Spiny Mouse (Western Saharan Spiny Mouse) – L. Granjon & K. Bâ | 219 |
| GENUS <i>Prionomys</i> Bates's Climbing Mouse – C. Denys | 189 | <i>Acomys cahirinus</i> Cairo Spiny Mouse (Northeast African Spiny Mouse) – F. Dieterlen | 220 |
| <i>Prionomys batesi</i> Bates's Climbing Mouse (Dollman's Tree Mouse) – C. Denys | 190 | <i>Acomys cineraceus</i> Grey Spiny Mouse (Heuglin's Spiny Mouse) – F. Dieterlen | 222 |
| GENUS <i>Steatomys</i> Fat Mice – A. Monadjem | 191 | <i>Acomys ignitus</i> Fiery Spiny Mouse – F. Dieterlen | 223 |
| <i>Steatomys bocagei</i> Bocage's Fat Mouse – D. C. D. Happold | 192 | <i>Acomys johannis</i> Johan's Spiny Mouse – L. Granjon | 224 |
| <i>Steatomys caurinus</i> North-western Fat Mouse – B. Sicard & J.-M. Duplantier | 193 | <i>Acomys kemp</i> Kemp's Spiny Mouse – F. Dieterlen | 225 |
| <i>Steatomys cuppedius</i> Dainty Fat Mouse – J.-M. Duplantier & B. Sicard | 194 | <i>Acomys louisae</i> Louise's Spiny Mouse – F. Dieterlen | 226 |
| <i>Steatomys jacksoni</i> Jackson's Fat Mouse – D. C. D. Happold | 195 | <i>Acomys mullah</i> Mullah Spiny Mouse – F. Dieterlen | 227 |
| <i>Steatomys krebsii</i> Krebs's Fat Mouse – A. Monadjem | 196 | <i>Acomys percivali</i> Percival's Spiny Mouse – S. Takata | 228 |
| <i>Steatomys opimus</i> Pousargues's Fat Mouse – D. C. D. Happold | 197 | <i>Acomys russatus</i> Golden Spiny Mouse – F. Dieterlen | 230 |
| <i>Steatomys parvus</i> Tiny Fat Mouse – A. Monadjem | 198 | <i>Acomys spinosissimus</i> Least Spiny Mouse (Southern Spiny Mouse) – D. C. D. Happold | 231 |
| <i>Steatomys pratensis</i> Common Fat Mouse – A. Monadjem | 199 | <i>Acomys subspinosus</i> Cape Spiny Mouse – E. R. Dempster | 233 |
| SUBFAMILY MYSTROMYINAE White-tailed Rat – M. D. Carleton & G. G. Musser | 201 | <i>Acomys wilsoni</i> Wilson's Spiny Mouse – S. Takata | 234 |
| GENUS <i>Mystromys</i> African White-tailed Rat – D. C. D. Happold | 201 | GENUS <i>Deomys</i> Rusty Link Rat – J. C. Ray & J. R. Malcolm | 235 |
| <i>Mystromys albicaudatus</i> African White-tailed Rat (Southern African Hamster) – M. Perrin | 201 | <i>Deomys ferrugineus</i> Rusty Link Rat (Congo Forest Rat) – J. C. Ray & J. R. Malcolm | 237 |
| SUBFAMILY PETROMYSCINAE Pygmy Rock Mice – M. D. Carleton & G. G. Musser | 203 | GENUS <i>Lophuromys</i> Brush-furred Rats – F. Dieterlen | 238 |
| GENUS <i>Petromyscus</i> Pygmy Rock Mice – C. G. Coetzee | 204 | <i>Lophuromys brevicaudus</i> Short-tailed Brush-furred Rat – L. A. Lavrenchenko | 240 |
| <i>Petromyscus barbouri</i> Barbour's Pygmy Rock Mouse (Namaqua Pygmy Rock Mouse) – C. G. Coetzee | 204 | <i>Lophuromys chrysopus</i> Golden-footed Brush-furred Rat (Ethiopian Forest Brush-furred Rat) – L. A. Lavrenchenko | 242 |
| <i>Petromyscus collinus</i> Pygmy Rock Mouse – C. G. Coetzee | 205 | <i>Lophuromys cinereus</i> Grey Brush-furred Rat – F. Dieterlen | 243 |
| <i>Petromyscus monticularis</i> Brukkaros Pygmy Rock Mouse (Short-eared Pygmy Rock Mouse) – C. G. Coetzee | 207 | <i>Lophuromys dieterleni</i> Dieterlen's Brush-furred Rat – F. Dieterlen | 244 |
| <i>Petromyscus shortridgei</i> Shortridge's Pygmy Rock Mouse (Kaokoveld Pygmy Rock Mouse) – C. G. Coetzee | 208 | <i>Lophuromys eisentrauti</i> Eisentraut's Brush-furred Rat – F. Dieterlen | 245 |
| | | <i>Lophuromys flavopunctatus</i> Yellow-spotted Brush-furred Rat (Buff-spotted Brush-furred Rat) – F. Dieterlen | 246 |

| | | | |
|--|-----|---|-----|
| <i>Lophuromys huttereri</i> Hutterer's Brush-furred Rat – F. Dieterlen | 248 | GENUS <i>Gerbillurus</i> Hairy-footed Gerbils – E. R. Dempster | 287 |
| <i>Lophuromys luteogaster</i> Buff-bellied Brush-furred Rat (Hatt's Brush-furred Rat) – F. Dieterlen | 249 | <i>Gerbillurus paeba</i> Pygmy Hairy-footed Gerbil (Paeba Hairy-footed Gerbil) – M. Perrin & E. R. Dempster | 288 |
| <i>Lophuromys medicaudatus</i> Medium-tailed Brush-furred Rat (Western Rift Brush-furred Rat) – F. Dieterlen | 250 | <i>Gerbillurus setzeri</i> Setzer's Hairy-footed Gerbil – M. Perrin & E. R. Dempster | 290 |
| <i>Lophuromys melanonyx</i> Black-clawed Brush-furred Rat – D. W. Yalden | 251 | <i>Gerbillurus tytonis</i> Dune Hairy-footed Gerbil – M. Perrin & E. R. Dempster | 291 |
| <i>Lophuromys nudicaudus</i> Fire-bellied Brush-furred Rat – F. Dieterlen | 252 | <i>Gerbillurus vallinus</i> Brush-tailed Hairy-footed Gerbil – M. Perrin & E. R. Dempster | 293 |
| <i>Lophuromys rahmi</i> Rahm's Brush-furred Rat – F. Dieterlen | 253 | GENUS <i>Gerbillus</i> Gerbils – L. Granjon | 295 |
| <i>Lophuromys roseveari</i> Rosevear's Brush-furred Rat (Mount Cameroon Brush-furred Rat) – F. Dieterlen | 254 | <i>Gerbillus acticola</i> Berbera Gerbil – D. C. D. Happold | 297 |
| <i>Lophuromys sikapusi</i> Rusty-bellied Brush-furred Rat – F. Dieterlen | 255 | <i>Gerbillus amoenus</i> Charming Gerbil (Pleasant Gerbil) – D. C. D. Happold | 298 |
| <i>Lophuromys woosnami</i> Woosnam's Brush-furred Rat – F. Dieterlen | 257 | <i>Gerbillus andersoni</i> Anderson's Gerbil – D. C. D. Happold | 299 |
| GENUS <i>Uranomys</i> Rudd's Brush-furred Mouse – D. C. D. Happold | 258 | <i>Gerbillus bottai</i> Botta's Gerbil – D. C. D. Happold | 300 |
| <i>Uranomys ruddi</i> Rudd's Brush-furred Mouse – D. C. D. Happold | 259 | <i>Gerbillus brockmani</i> Brockman's Gerbil – D. C. D. Happold | 301 |
| SUBFAMILY GERBILLINAE Gerbils and Jirds – M. D. Carleton & G. G. Musser | 260 | <i>Gerbillus campestris</i> North African Gerbil – D. C. D. Happold | 302 |
| GENUS <i>Ammodillus</i> Ammodile – D. C. D. Happold | 262 | <i>Gerbillus cosensi</i> Cosens's Gerbil – D. C. D. Happold | 304 |
| <i>Ammodillus imbellis</i> Ammodile (Walo) – D. C. D. Happold | 263 | <i>Gerbillus dasyurus</i> Wagner's Gerbil – D. C. D. Happold | 304 |
| GENUS <i>Desmodilliscus</i> Brauer's Dwarf Gerbil – L. Granjon | 264 | <i>Gerbillus dunni</i> Dunn's Gerbil – D. C. D. Happold | 306 |
| <i>Desmodilliscus braueri</i> Brauer's Dwarf Gerbil (Pouched Gerbil) – L. Granjon | 264 | <i>Gerbillus floweri</i> Flower's Gerbil – L. Granjon | 307 |
| GENUS <i>Desmodillus</i> Cape Short-tailed Gerbil – J. A. J. Nel | 266 | <i>Gerbillus gerbillus</i> Lesser Egyptian Gerbil (Small Egyptian Gerbil) – L. Granjon | 308 |
| <i>Desmodillus auricularis</i> Cape Short-tailed Gerbil (Namaqua Gerbil) – J. A. J. Nel | 267 | <i>Gerbillus harwoodi</i> Harwood's Gerbil – D. C. D. Happold | 309 |
| GENUS <i>Gerbilliscus</i> Gerbils – L. Granjon & E. R. Dempster | 268 | <i>Gerbillus henleyi</i> Henley's Gerbil – L. Granjon | 310 |
| <i>Gerbilliscus afra</i> Cape Gerbil – E. R. Dempster | 270 | <i>Gerbillus hesperinus</i> Moroccan Gerbil – D. C. D. Happold | 311 |
| <i>Gerbilliscus boehmi</i> Boehm's Gerbil – D. C. D. Happold | 272 | <i>Gerbillus hoogstraali</i> Hoogstraal's Gerbil – D. C. D. Happold | 312 |
| <i>Gerbilliscus brantsii</i> Highveld Gerbil – E. R. Dempster | 273 | <i>Gerbillus juliani</i> Julian's Gerbil – D. C. D. Happold | 313 |
| <i>Gerbilliscus gambianus</i> Gambian Gerbil – J.-M. Duplantier & L. Granjon | 274 | <i>Gerbillus latastei</i> Lataste's Gerbil – D. C. D. Happold | 314 |
| <i>Gerbilliscus guineae</i> Guinea Gerbil – L. Granjon & J.-M. Duplantier | 276 | <i>Gerbillus lowei</i> Lowe's Gerbil – D. C. D. Happold | 315 |
| <i>Gerbilliscus inclusus</i> Gorongoza Gerbil – E. R. Dempster | 277 | <i>Gerbillus mackilligini</i> Mackilligin's Gerbil – D. C. D. Happold | 316 |
| <i>Gerbilliscus kempfi</i> Kemp's Gerbil (Northern Savanna Gerbil) – D. C. D. Happold | 278 | <i>Gerbillus maghrebi</i> Maghreb Gerbil – S. Aulagnier | 317 |
| <i>Gerbilliscus leucogaster</i> Bushveld Gerbil – E. R. Dempster | 279 | <i>Gerbillus nancillus</i> Sudan Gerbil – L. Granjon | 318 |
| <i>Gerbilliscus nigricaudus</i> Black-tailed Gerbil – D. C. D. Happold | 281 | <i>Gerbillus nanus</i> Dwarf Gerbil (Baluchistan Gerbil) – L. Granjon | 318 |
| <i>Gerbilliscus phillipsi</i> Phillips's Gerbil – D. C. D. Happold | 283 | <i>Gerbillus nigeriae</i> Nigerian Gerbil – B. Sicard | 320 |
| <i>Gerbilliscus robustus</i> Fringe-tailed Gerbil – D. C. D. Happold | 284 | <i>Gerbillus occiduus</i> Occidental Gerbil – L. Granjon | 321 |
| <i>Gerbilliscus validus</i> Savanna Gerbil (Southern Savanna Gerbil) – D. C. D. Happold | 285 | <i>Gerbillus percivali</i> Percival's Gerbil – D. C. D. Happold | 322 |
| | | <i>Gerbillus perpallidus</i> Pale Gerbil – D. C. D. Happold | 323 |
| | | <i>Gerbillus pulvinatus</i> Cushioned Gerbil (Rhoad's Gerbil) – D. C. D. Happold | 324 |
| | | <i>Gerbillus pusillus</i> Least Gerbil – D. C. D. Happold | 325 |
| | | <i>Gerbillus pyramidum</i> Greater Egyptian Gerbil – L. Granjon | 325 |
| | | <i>Gerbillus rosalia</i> Rosalind's Gerbil (Rosalinda Gerbil) – D. C. D. Happold | 327 |
| | | <i>Gerbillus rupicola</i> Rock Gerbil – L. Granjon | 328 |

A. V. Linzey, C. T. Chimimba & M. H. Kesner | 373 |
| GENUS <i>Microdillus</i> Peel's Pygmy Gerbil – D. C. D. Happold | 339 | <i>Aethomys silindensis</i> Selinda Veld Rat (Selinda Aethomys) –
C. T. Chimimba, A. V. Linzey & M. H. Kesner | 374 |
| <i>Microdillus peeli</i> Peel's Pygmy Gerbil (Somali Pygmy
Gerbil) – D. C. D. Happold | 340 | <i>Aethomys stannarius</i> West African Veld Rat (West African
Aethomys) – A. V. Linzey, C. T. Chimimba &
M. H. Kesner | 375 |
| GENUS <i>Pachyuromys</i> Fat-tailed Jird – D. C. D. Happold | 341 | <i>Aethomys thomasi</i> Thomas's Veld Rat (Thomas's Aethomys)
– C. T. Chimimba, A. V. Linzey & M. H. Kesner | 376 |
| <i>Pachyuromys duprasi</i> Fat-tailed Jird – D. C. D. Happold | 341 | GENUS <i>Apodemus</i> Field Mice – C. Denys | 377 |
| GENUS <i>Psammomys</i> Sand Rats – E. Fichet-Calvet | 343 | <i>Apodemus sylvaticus</i> Long-tailed Field Mouse (Wood
Mouse) – C. Denys | 378 |
| <i>Psammomys obesus</i> Fat Sand Rat – E. Fichet-Calvet | 344 | GENUS <i>Arvicanthis</i> Grass Rats – L. Granjon & J.-F. Ducroz | 379 |
| <i>Psammomys vexillaris</i> Pale Sand Rat (Lesser Sand Rat) –
E. Fichet-Calvet | 346 | <i>Arvicanthis abyssinicus</i> Ethiopian Grass Rat (Abyssinian
Grass Rat) – Afework Bekele | 381 |
| GENUS <i>Sekeetamys</i> Bushy-tailed Jird – C. Denys | 347 | <i>Arvicanthis ansorgei</i> Ansorge's Grass Rat (Sudanian
Arvicanthis) – L. Granjon & J.-F. Ducroz | 382 |
| <i>Sekeetamys calurus</i> Bushy-tailed Jird – C. Denys | 347 | <i>Arvicanthis blicki</i> Blick's Grass Rat – Afework Bekele | 383 |
| GENUS <i>Taterillus</i> Taterils (Gerbils) – L. Granjon & G. Dobigny | 349 | <i>Arvicanthis nairobae</i> Nairobi Grass Rat – S. Takata | 384 |
| <i>Taterillus arenarius</i> Sand Tateril (Robbins's Tateril) –
L. Granjon & G. Dobigny | 350 | <i>Arvicanthis neumanni</i> Neumann's Grass Rat (Somali Grass
Rat) – Afework Bekele | 386 |
| <i>Taterillus congicus</i> Congo Tateril – L. Granjon & G. Dobigny | 351 | <i>Arvicanthis niloticus</i> Nile Grass Rat (Unstriped Grass Rat) –
L. Granjon, Afework Bekele & J.-F. Ducroz | 387 |
| <i>Taterillus emini</i> Emin's Tateril – L. Granjon & G. Dobigny | 352 | <i>Arvicanthis rufinus</i> Rufous Grass Rat (Guinean Grass Rat)
– L. Granjon & J.-F. Ducroz | 388 |
| <i>Taterillus gracilis</i> Slender Tateril (Gracile Tateril) –
L. Granjon & G. Dobigny | 353 | GENUS <i>Colomys</i> African Water Rat – F. Dieterlen | 389 |
| <i>Taterillus lacustris</i> Lake Chad Tateril – L. Granjon &
G. Dobigny | 354 | <i>Colomys goslingi</i> African Water Rat (Velvet Mouse, African
Wading Rat) – F. Dieterlen | 390 |
| <i>Taterillus petteri</i> Petter's Tateril – Bruno Sicard | 355 | GENUS <i>Dasyomys</i> Shaggy Rats – M. D. Carleton | 392 |
| <i>Taterillus pygargus</i> Senegal Tateril (Cuvier's Tateril) –
L. Granjon & G. Dobigny | 356 | <i>Dasyomys foxi</i> Fox's Shaggy Rat – M. D. Carleton | 394 |
| <i>Taterillus tranieri</i> Tranier's Tateril – G. Dobigny & L. Granjon | 357 | <i>Dasyomys incommutus</i> Common Shaggy Rat – N. Pillay | 395 |
| SUBFAMILY LEIMACOMYINAE Büttner's Forest Mouse –
G. G. Musser & M. D. Carleton | 358 | <i>Dasyomys montanus</i> Montane Shaggy Rat – M. D. Carleton | 396 |
| GENUS <i>Leimacomys</i> Büttner's Forest Mouse – F. Dieterlen | 359 | <i>Dasyomys nudipes</i> Angolan Shaggy Rat – M. D. Carleton | 397 |
| <i>Leimacomys buettneri</i> Büttner's Forest Mouse (Büttner's
Togo Mouse) – F. Dieterlen | 359 | <i>Dasyomys rufulus</i> Rufous Shaggy Rat – J.-M. Duplantier | 399 |
| SUBFAMILY MURINAE Rats and Mice – G. G. Musser &
M. D. Carleton | 361 | GENUS <i>Dephomys</i> Defua Rat – D. C. D. Happold | 400 |
| GENUS <i>Aethomys</i> Veld Rats – C. T. Chimimba,
A. V. Linzey & M. H. Kesner | 362 | <i>Dephomys defua</i> Defua Rat – D. C. D. Happold | 400 |
| <i>Aethomys bocagei</i> Bocage's Veld Rat (Bocage's Aethomys) –
C. T. Chimimba, A. V. Linzey & M. H. Kesner | 364 | GENUS <i>Desmomys</i> Scrub Rats – D. C. D. Happold | 402 |
| <i>Aethomys chrysophilus</i> Red Veld Rat (Red Aethomys) –
A. V. Linzey, M. H. Kesner & C. T. Chimimba | 365 | <i>Desmomys harringtoni</i> Harrington's Scrub Rat
(Harrington's Desmomys) – Afework Bekele | 402 |
| <i>Aethomys granti</i> Grant's Veld Rat (Grant's Aethomys) –
C. T. Chimimba, A. V. Linzey & M. H. Kesner | 367 | <i>Desmomys yaldeni</i> Yalden's Scrub Rat (Yalden's Desmomys)
– D. W. Yalden | 403 |
| <i>Aethomys hindei</i> Hinde's Veld Rat (Hinde's Aethomys) –
A. V. Linzey, C. T. Chimimba & M. H. Kesner | 368 | GENUS <i>Grammomys</i> Thicket Rats – F. Dieterlen | 404 |
| <i>Aethomys ineptus</i> Tete Veld Rat (Tete Aethomys) –
A. V. Linzey, M. H. Kesner & C. T. Chimimba | 369 | <i>Grammomys aridulus</i> Jebel Marra Thicket Rat (Arid
Woodland Grammomys) – F. Dieterlen | 406 |
| <i>Aethomys kaiseri</i> Kaiser's Veld Rat (Kaiser's Aethomys) –
A. V. Linzey, C. T. Chimimba & M. H. Kesner | 370 | <i>Grammomys buntingi</i> Bunting's Thicket Rat (Bunting's
Grammomys) – D. C. D. Happold | 407 |
| <i>Aethomys namaquensis</i> Namaqua Veld Rat (Namaqua
Aethomys) – M. H. Kesner, A. V. Linzey & C. T. Chimimba | 371 | <i>Grammomys caniceps</i> Grey-headed Thicket Rat (Grey-
headed Grammomys) – R. Hutterer | 408 |
| | | <i>Grammomys cometes</i> Mozambique Thicket Rat
(Mozambique Grammomys) – F. Dieterlen | 409 |

| | | | |
|---|-----|---|-----|
| <i>Grammomys dolichurus</i> Woodland Thicket Rat (Common Grammomys) – D. C. D. Happold | 410 | GENUS <i>Lemniscomys</i> Grass Mice – M. D. Carleton | 441 |
| <i>Grammomys dryas</i> Albertine Rift Thicket Rat (Albertine Rift Grammomys) – S. O. Bober & J. C. Kerbis Peterhans | 411 | <i>Lemniscomys barbarus</i> Barbary Grass Mouse (Barbary Lemniscomys) – D. C. D. Happold | 443 |
| <i>Grammomys gigas</i> Giant Thicket Rat (Mount Kenya Grammomys) – F. Dieterlen | 412 | <i>Lemniscomys bellieri</i> Bellier's Grass Mouse (Bellier's Lemniscomys) – E. Van der Straeten | 444 |
| <i>Grammomys ibeanus</i> East African Thicket Rat (East African Grammomys) – F. Dieterlen | 413 | <i>Lemniscomys griselda</i> Griselda's Grass Mouse (Griselda's Lemniscomys) – A. Monadjem | 445 |
| <i>Grammomys kuru</i> Shining Thicket Rat (Eastern Rainforest Grammomys) – D. C. D. Happold | 414 | <i>Lemniscomys hoogstraali</i> Hoogstraal's Grass Mouse (Hoogstraal's Lemniscomys) – F. Dieterlen | 446 |
| <i>Grammomys macmillani</i> Macmillan's Thicket Rat (Macmillan's Grammomys) – F. Dieterlen | 416 | <i>Lemniscomys linulus</i> Senegal Grass Mouse (Senegal Lemniscomys) – E. Van der Straeten | 447 |
| <i>Grammomys minnae</i> Ethiopian Thicket Rat (Ethiopian Grammomys) – D. W. Yalden | 417 | <i>Lemniscomys macculus</i> Buffoon Grass Mouse (Buffoon Lemniscomys) – F. Dieterlen | 448 |
| GENUS <i>Heimyscus</i> African Smoky Mouse – J. C. Ray & J. R. Malcolm | 418 | <i>Lemniscomys mittendorfi</i> Mittendorf's Grass Mouse (Mittendorf's Lemniscomys) – E. Van der Straeten | 449 |
| <i>Heimyscus fumosus</i> African Smoky Mouse – J. C. Ray & J. R. Malcolm | 418 | <i>Lemniscomys rosalia</i> Single-striped Grass Mouse (Single-striped Lemniscomys) – A. Monadjem | 449 |
| GENUS <i>Hybomys</i> Forest Mice – M. D. Carleton | 420 | <i>Lemniscomys roseveari</i> Rosevear's Grass Mouse (Rosevear's Lemniscomys) – E. Van der Straeten | 451 |
| <i>Hybomys badius</i> Cameroon Forest Mouse (Cameroon Highland Hybomys) – R. Hutterer | 422 | <i>Lemniscomys striatus</i> Striated Grass Mouse (Striated Lemniscomys) – D. C. D. Happold | 452 |
| <i>Hybomys basillii</i> Basilio's Forest Mouse (Bioko Hybomys) – R. Hutterer | 423 | <i>Lemniscomys zebra</i> Zebra Grass Mouse (Heuglin's Lemniscomys) – D. C. D. Happold & F. Dieterlen | 454 |
| <i>Hybomys lunaris</i> Rwenzori Forest Mouse (Rwenzori Hybomys) – F. Dieterlen | 423 | GENUS <i>Malacomys</i> Swamp Rats – D. C. D. Happold | 455 |
| <i>Hybomys planifrons</i> Liberian Forest Mouse (Liberian Forest Hybomys) – M. D. Carleton | 424 | <i>Malacomys cansdalei</i> Cansdale's Swamp Rat (Cansdale's Malacomys) – D. C. D. Happold | 456 |
| <i>Hybomys trivirgatus</i> Three-striped Forest Mouse (West African Hybomys) – M. D. Carleton & D. C. D. Happold | 425 | <i>Malacomys edwardsi</i> Edwards's Swamp Rat (Edwards's Malacomys) – D. C. D. Happold | 457 |
| <i>Hybomys univittatus</i> One-striped Forest Mouse (Peters's Hybomys) – J. C. Ray | 427 | <i>Malacomys longipes</i> Long-footed Swamp Rat (Common Malacomys) – D. C. D. Happold | 458 |
| GENUS <i>Hylomyscus</i> Wood Mice – F. Dieterlen | 429 | GENUS <i>Mastomys</i> Multimammate Mice – H. Leirs | 460 |
| <i>Hylomyscus aeta</i> Beaded Wood Mouse (Beaded Hylomyscus) – J. C. Ray & J. R. Malcolm | 430 | <i>Mastomys awashensis</i> Awash Multimammate Mouse (Awash Mastomys) – L. A. Lavrenchenko & H. Leirs | 462 |
| <i>Hylomyscus alleni</i> Allen's Wood Mouse (Allen's Hylomyscus) – J. C. Ray | 431 | <i>Mastomys coucha</i> Southern African Multimammate Mouse (Southern African Mastomys) – H. Leirs | 463 |
| <i>Hylomyscus baeri</i> Baer's Wood Mouse (Baer's Hylomyscus) – D. C. D. Happold | 433 | <i>Mastomys erythroleucus</i> Guinea Multimammate Mouse (Reddish-white Mastomys) – H. Leirs | 464 |
| <i>Hylomyscus carillus</i> Angolan Wood Mouse (Angolan Hylomyscus) – D. C. D. Happold | 433 | <i>Mastomys huberti</i> Hubert's Multimammate Mouse (Hubert's Mastomys) – H. Leirs | 465 |
| <i>Hylomyscus denniae</i> Montane Wood Mouse (Montane Hylomyscus) – F. Dieterlen | 434 | <i>Mastomys kollmannspergeri</i> Kollmannsperger's Multimammate Mouse (Kollmannsperger's Mastomys) – H. Leirs | 467 |
| <i>Hylomyscus grandis</i> Large Wood Mouse (Mount Oku Hylomyscus) – R. Hutterer | 436 | <i>Mastomys natalensis</i> Natal Multimammate Mouse (Natal Mastomys) – H. Leirs | 468 |
| <i>Hylomyscus parvus</i> Lesser Wood Mouse (Lesser Hylomyscus) – J.-M. Duplantier | 437 | <i>Mastomys pernanus</i> Dwarf Multimammate Mouse (Dwarf Mastomys) – H. Leirs | 470 |
| <i>Hylomyscus stella</i> Stella Wood Mouse (Stella Hylomyscus) – F. Dieterlen | 438 | <i>Mastomys shortridgei</i> Shortridge's Multimammate Mouse (Shortridge's Mastomys) – H. Leirs | 471 |
| GENUS <i>Lamottemys</i> Mount Oku Rat – R. Hutterer | 439 | GENUS <i>Muriculus</i> Ethiopian Striped Mouse – D. W. Yalden | 472 |
| <i>Lamottemys okuensis</i> Mount Oku Rat (Mount Oku Lamottemys) – R. Hutterer | 440 | <i>Muriculus imberbis</i> Ethiopian Striped Mouse – D. W. Yalden | 472 |
| | | GENUS <i>Mus</i> Old World Mice and Pygmy Mice – D. C. D. Happold & F. Veyrunes | 473 |
| | | <i>Mus baoulei</i> Baoule Pygmy Mouse – L. Granjon | 476 |

| | | | |
|--|-----|---|-----|
| <i>Mus bufo</i> Toad Pygmy Mouse (Rwenzori Mouse) – F. Dieterlen | 477 | <i>Pelomys campanae</i> Angolan Creek Rat (Angolan Pelomys) – F. Dieterlen | 514 |
| <i>Mus callewaerti</i> Callewaert's Pygmy Mouse – D. C. D. Happold | 478 | <i>Pelomys fallax</i> East African Creek Rat (East African Pelomys) – F. Dieterlen | 515 |
| <i>Mus goundae</i> Gounda River Pygmy Mouse – F. Petter | 479 | <i>Pelomys hopkinsi</i> Hopkins's Creek Rat (Hopkins's Pelomys) – F. Dieterlen | 517 |
| <i>Mus haussa</i> Hausa Pygmy Mouse – F. Petter | 480 | <i>Pelomys isseli</i> Ssesse Islands Creek Rat (Lake Victoria Pelomys) – F. Dieterlen | 518 |
| <i>Mus indutus</i> Desert Pygmy Mouse – A. Monadjem | 481 | <i>Pelomys minor</i> Least Creek Rat (Least Pelomys) – F. Dieterlen | 519 |
| <i>Mus mahomet</i> Mahomet Pygmy Mouse – D. W. Yalden | 482 | GENUS <i>Praomys</i> Soft-furred Mice – D. C. D. Happold | 519 |
| <i>Mus mattheyi</i> Matthey's Pygmy Mouse – F. Petter | 483 | <i>Praomys daltoni</i> Dalton's Soft-furred Mouse (Dalton's Praomys) – L. Granjon | 522 |
| <i>Mus minutoides</i> Tiny Pygmy Mouse – A. Monadjem | 484 | <i>Praomys degraaffi</i> De Graaff's Soft-furred Mouse (De Graaff's Praomys) – J. C. Kerbis Peterhans & S. O. Bober | 523 |
| <i>Mus musculoides</i> West African Pygmy Mouse – D. C. D. Happold | 486 | <i>Praomys delectorum</i> Delicate Soft-furred Mouse (East African Praomys) – D. C. D. Happold | 524 |
| <i>Mus musculus</i> House Mouse – D. C. D. Happold | 487 | <i>Praomys derooi</i> De Roo's Soft-furred Mouse (De Roo's Praomys) – L. Granjon | 526 |
| <i>Mus neavei</i> Neave's Pygmy Mouse – F. Petter | 489 | <i>Praomys hartwigi</i> Hartwig's Soft-furred Mouse (Hartwig's Praomys) – R. Hutterer | 527 |
| <i>Mus orangiae</i> Orange Pygmy Mouse – A. Monadjem | 490 | <i>Praomys jacksoni</i> Jackson's Soft-furred Mouse (Jackson's Praomys) – F. Dieterlen | 527 |
| <i>Mus oubanguii</i> Oubangui Pygmy Mouse – F. Petter | 491 | <i>Praomys lukolelae</i> Lukolela Soft-furred Mouse (Lukolela Praomys) – D. C. D. Happold | 529 |
| <i>Mus setulosus</i> Peters's Pygmy Mouse – D. C. D. Happold | 492 | <i>Praomys minor</i> Least Soft-furred Mouse (Least Praomys) – E. Van der Straeten | 530 |
| <i>Mus setzeri</i> Setzer's Pygmy Mouse – A. Monadjem | 493 | <i>Praomys misonnei</i> Misonne's Soft-furred Mouse (Misonne's Praomys) – F. Dieterlen | 531 |
| <i>Mus sorella</i> Sorella Pygmy Mouse (Thomas's Pygmy Mouse) – F. Petter | 494 | <i>Praomys morio</i> Cameroon Soft-furred Mouse (Cameroon Praomys) – D. C. D. Happold | 532 |
| <i>Mus spretus</i> Algerian Mouse (Western Mediterranean Mouse) – D. C. D. Happold | 495 | <i>Praomys mutoni</i> Riverine Soft-furred Mouse (Masako Soft-furred Mouse, Riverine Praomys) – E. Van der Straeten | 533 |
| <i>Mus tenellus</i> Delicate Pygmy Mouse – F. Petter | 496 | <i>Praomys obscurus</i> Obscure Soft-furred Mouse (Gotel Mountain Praomys) – R. Hutterer | 534 |
| <i>Mus triton</i> Grey-bellied Pygmy Mouse – F. Dieterlen & D. C. D. Happold | 497 | <i>Praomys petteri</i> Petter's Soft-furred Mouse (Petter's Praomys) – E. Van der Straeten | 535 |
| GENUS <i>Mylomys</i> Mill Rats (Three-toed Grass Rats) – F. Dieterlen | 499 | <i>Praomys rostratus</i> West African Soft-furred Mouse (West African Praomys) – E. Van der Straeten | 536 |
| <i>Mylomys dybowskii</i> Dybowski's Mill Rat (Dybowski's Three-toed Grass Rat, Common Mylomys) – F. Dieterlen | 500 | <i>Praomys tullbergi</i> Tullberg's Soft-furred Mouse (Tullberg's Praomys) – D. C. D. Happold | 537 |
| <i>Mylomys rex</i> King Mill Rat (Ethiopian Three-toed Grass Rat, Ethiopian Mylomys) – D. W. Yalden | 501 | <i>Praomys verschureni</i> Verschuren's Soft-furred Mouse (Verschuren's Praomys) – F. Dieterlen | 538 |
| GENUS <i>Myomyscus</i> Meadow Mice – D. C. D. Happold | 502 | GENUS <i>Rattus</i> Rats – D. C. D. Happold | 539 |
| <i>Myomyscus angolensis</i> Angolan Meadow Mouse (Angolan Myomyscus) – H. Leirs | 503 | <i>Rattus norvegicus</i> Brown Rat (Norway Rat) – D. C. D. Happold | 540 |
| <i>Myomyscus brockmani</i> Brockman's Meadow Mouse (Smoky Meadow Mouse, Brockman's Myomyscus) – D. C. D. Happold | 504 | <i>Rattus rattus</i> Black Rat – D. C. D. Happold | 541 |
| <i>Myomyscus verreauxii</i> Verreaux's Meadow Mouse (White-footed Mouse) – D. C. D. Happold | 505 | GENUS <i>Rhabdomys</i> Four-striped Grass Mouse – D. C. D. Happold | 544 |
| GENUS <i>Nesokia</i> Bandicoot Rats – D. C. D. Happold | 506 | <i>Rhabdomys pumilio</i> Four-striped Grass Mouse – D. C. D. Happold | 545 |
| <i>Nesokia indica</i> Short-tailed Bandicoot Rat (Egyptian Pest Rat) – D. C. D. Happold | 506 | GENUS <i>Stenocephalemys</i> Ethiopian Rats – D. W. Yalden | 547 |
| GENUS <i>Nilopegamys</i> Ethiopian Water Rat – D. C. D. Happold | 508 | <i>Stenocephalemys albipes</i> White-footed Ethiopian Rat (White-footed Stenocephalemys) – Afework Bekele | 549 |
| <i>Nilopegamys plumbeus</i> Ethiopian Water Rat – D. C. D. Happold | 508 | | |
| GENUS <i>Oenomys</i> Rufous-nosed Rats – F. Dieterlen | 509 | | |
| <i>Oenomys hypoxanthus</i> Common Rufous-nosed Rat (Common Oenomys) – F. Dieterlen | 510 | | |
| <i>Oenomys ornatus</i> West African Rufous-nosed Rat (West African Oenomys) – F. Dieterlen | 512 | | |
| GENUS <i>Pelomys</i> Creek Rats – F. Dieterlen | 513 | | |

| | | | |
|---|-----|--|-----|
| <i>Stenocephalemys albocaudata</i> White-tailed Ethiopian Rat (White-tailed <i>Stenocephalemys</i>) – D. W. Yalden | 550 | <i>Otomys unisulcatus</i> Karoo Vlei Rat (Bush Karoo Rat) – T. P. Jackson | 594 |
| <i>Stenocephalemys griseicauda</i> Grey-tailed Ethiopian Rat (Grey-tailed <i>Stenocephalemys</i>) – D. W. Yalden | 552 | GENUS <i>Parotomys</i> Whistling Rats – T. P. Jackson | 596 |
| <i>Stenocephalemys rupp</i> Rupp's Ethiopian Rat (Gughe Highlands Rat, Rupp's <i>Stenocephalemys</i>) – D. W. Yalden | 553 | <i>Parotomys brantsii</i> Brants's Whistling Rat – T. P. Jackson | 597 |

Series Acknowledgements

Jonathan Kingdon, David Happold, Thomas Butynski,

Michael Hoffmann, Meredith Happold and Jan Kalina

The editors wish to record their thanks to all the authors who have contributed to *Mammals of Africa* for their expert work and for their patience over the very protracted period that these volumes have taken to materialize. We also thank the numerous reviewers who have read and commented on earlier drafts of this work.

We are also grateful for the generosity of our sponsoring patrons, whose names are recorded on our title pages, who have made the publication of these volumes possible.

Special thanks are due to Andy Richford, the Publishing Editor at Academic Press, who initiated and supported our work on *Mammals of Africa*, from its inception up to the point where Bloomsbury Publishing assumed responsibility, and to Nigel Redman (Head of Natural History at Bloomsbury), David and Namrita Price-Goodfellow at D & N Publishing, and the whole production team who have brought this work to fruition. We also acknowledge, with thanks, Elaine Leek who copy-edited every volume. We are grateful to Chuck Crumly, formerly of Academic Press and now the University of California Press, for being our active advocate during difficult times.

We have benefited from the knowledge and assistance of scholars and staff at numerous museums, universities and other institutions all over the world. More detailed and personal acknowledgements follow from the editors of each volume.

The editors are also grateful to the coordinating team of the Global Mammal Assessment, an initiative of the International Union for Conservation of Nature (IUCN), which organized a series of workshops to review the taxonomy and current distribution maps for many species of African mammals. These workshops were hosted by the Zoological Society of London, Disney's Animal Kingdom, the Owston's Palm Civet Conservation Programme, and the Wildlife Conservation Research Unit at the University of Oxford; additionally, IUCN conducted a review of the maps for the large mammals by the Specialist Groups of the Species Survival Commission. We owe a particular word of thanks to all the staff and personnel who made these workshops possible, and to the participants who attended and provided their time and expertise to this important initiative. We also thank IUCN for permission to use data from the *IUCN Red List of Threatened Species*.

Acknowledgements for Volume III

D. C. D. Happold

I owe a great debt of gratitude to the many people who have helped and encouraged me with my research on African small mammals for nearly 50 years and hence have contributed enormously to this volume. My interest in rodents (and other small mammals) began when I spent three months in 1959 at the 'Institut pour la Recherche Scientifique d'Afrique Centrale' in the then Belgian Congo; here I met Urs Rahm whose enthusiasm for small mammals has been an inspiration ever since. When I was beginning my research, the following colleagues were a marvellous source of inspiration: Frank Ansell †, Mike Delany, Fritz Dieterlen, Harry Hoogstraal †, Dieter Kock, Waldo Meester †, Xavier Misonne †, Francis Petter †, Don Rosevear †, Hank Setzer † and Reay Smithers †. Since then, other colleagues and friends have given advice, sent books and publications, and encouraged me in my studies. I also acknowledge the many collectors who, from the nineteenth century onwards, collected specimens, often in remote parts of Africa and often under appallingly difficult conditions, and sent them back to museums in Britain, Europe and North America where they still provide invaluable information. I am also most grateful to my colleagues (many of whom are authors of profiles in this volume) who have given very generously of their time and knowledge to make this volume possible. [† Deceased]

This volume owes a great deal to the museums that house specimens of African small mammals. For many years, I have visited museums whenever the opportunity has occurred, and I am most grateful to the curators and their assistants who have helped me during my visits: David Harrison, Paul Bates and Malcolm Pearch (Harrison Zoological Institute, Sevenoaks, England), Francis Petter and Jacques Cuisin (Museum National d'Histoire Naturelle, Paris, France), Lydia Kigo (National Museum of Kenya, Nairobi, Kenya), Wim Wendelen (Royal Museum of Central Africa, Tervuren, Belgium), Judith Eger (Royal Ontario Museum, Toronto, Canada), Dieter Kock (Senckenberg Museum, Frankfurt, Germany), Teresa Kearney and Christian Chimimba (Transvaal Museum, Pretoria, South Africa) and Rainer Hutterer (Museum Alexander Koenig, Bonn, Germany). I owe a particular debt of gratitude to the Natural History Museum, London, England (formerly British Museum of Natural History), especially Gordon Corbet, Robert Hayman †, John Edwards Hill †, Paula Jenkins, Jean Ingles, Daphne Hills and Louise Tomsett who have allowed me (since 1964) to examine the collections and have assisted me in numerous ways. Particular thanks are due to Michael and Mona Ensor and Sara Churchfield in London, the Ostermeyer and Schlöder families in Bonn, our friends in Corniche Verte in Brussels, and Mike

and Anne-Marie Swift in Nairobi, who provided welcoming homes and sustenance after busy days in museums.

I wish to thank the various universities where I have been employed, for their financial (and other) support for my studies on African mammals: Australian National University, Canberra, Australia; university of Ibadan, Nigeria; University of Khartoum, Sudan; and University of Malawi, Zomba, Malawi. The Australian Research Grants Committee also provided funds for my more recent work in Malawi. Very special thanks are due to my wife Meredith who has assisted me as research assistant, collaborator, co-author and reviewer; in fact, a lot of our research would not have been accomplished without her enthusiasm and encouragement.

This volume would not have been possible without the contributions and invaluable collaboration from the authors themselves. Many authors had other commitments and found it extremely hard to find the time for writing profiles. Great credit is due to such authors, and to those who wrote numerous profiles, for their dedication and perseverance. My thanks are also due to the many reviewers (listed here in alphabetical order) who reviewed profiles and gave specialist advice for this volume: Corne Anderson, Dick Ashford, Paul Bates, Afework Bekele, Nigel Bennett, Mike Carleton, Christian Chimimba, Viola Clausnitzer, Neels Coetzee, Norbert Cordeiro, Marco Corti, José Crawford-Cabral, Fritz Dieterlen, Colleen Downs, Jean-Marc Duplantier, Louise Emmons, Chris G. Faulkes, Trish Fleming, Laurent Granjon, Mike J. Griffin, Peter Grubb, Barbara Herzig-Straschil, Tim Jackson, Jenny Jarvis, Graham Kerley, Michael Knight, Dieter Kock, Leonid Lavrenchenko, Emile Lecompte, Herwig Leirs, Jay Malcolm, Sarita Maree, Andrea Mess, Ara Monadjem, Guy Musser, Jan Nel, Dean Peinke, Mike Perrin, Francis Petter, Victor Rambau, Galen Rathbun, Brian Robbins, Lynn Robbins, Carsten Schradin, Anje Schunke, Claudio Sillero-Zubiri, William Stanley, Radim Sumbera, Peter Taylor, Michel Thèvenot, Michel Tranier, Erik Van der Straeten, Frederic Veyrunes, Derek Yalden and Truman Young. Anke Hoffman kindly provided most of the German names for the small mammals in this volume.

Finally, I wish to express my thanks to the coordinating team of the Global Mammal Assessment, an initiative of the International Union for the Conservation of Nature (IUCN) and The Zoological Society of London who organized the workshops referred to in the General Acknowledgements. Also, I am most grateful to Elaine Leek who did a magnificent job copy-editing the text of this volume, and to Zoe Cokeliss who digitized all the distribution maps of the small mammals supplied by the authors.

Mammals of Africa: *An Introduction and Guide*

David Happold, Michael Hoffmann, Thomas Butynski and Jonathan Kingdon

Mammals of Africa is a series of six volumes that describes, in detail, every extant species of African land mammal that was recognized at the time the profiles were written (Table 1). This is the first time that such an extensive coverage has been attempted; all previous books and field guides have either been regional in coverage, or have described a selection of mammal species – usually the larger species. These volumes demonstrate the diversity of Africa's mammals, summarize what is known about the distribution, ecology, behaviour and conservation status of each species, and serves as a guide to identification.

Africa has changed greatly in recent decades because of increases in human populations, exploitation of natural resources, agricultural development and urban expansion. Throughout the continent, extensive areas of forest have been destroyed and much of the forest that remains is degraded and fragmented. Savanna habitats have been altered by felling of trees and development for agriculture. Many of the drier areas are threatened with desertification. As a result, the abundance and geographic ranges of many species of mammals have declined – some marginally, some catastrophically, some to extinction. Hence, it seems appropriate that our knowledge of each

species is recorded now, on a pan-African basis, because the next few decades will see even more human-induced changes. How such changes will affect each mammalian species is uncertain, but this series of volumes will act as a baseline for assessing future change.

The study of African mammals has taken several stages. During the era of European exploration and colonization, the scientific study of African mammals was largely descriptive. Specimens that were sent to museums were described and named. As more specimens became available, and from different parts of the Continent, there was increasing interest in distribution and abundance, and in the ecological and behavioural attributes of species and communities. At first, it was the largest and most easily observed species that were the focus of most studies, but as new methodologies and equipment became available, the smaller, seldom seen, secretive species became better known. Many species were studied because of their suspected role in diseases of humans and livestock, and because they were proven or potential 'pests' in agricultural systems. During the past decade or so, there has been greater emphasis on the karyotypic and molecular/genetic characters of species. These studies have produced a wealth of information, especially during the past 40 years or so. These volumes are not only a distillation of the huge literature that now exists on African mammals, but also of much previously unpublished information.

There is a huge discrepancy among species in the amount of information available. Some species have been studied extensively for many years, especially the so-called 'game species', some species of primates, and a few species that are widespread and/or easily observed. In contrast, other species are known only by one or a few specimens, and almost nothing is known about them. Likewise, some areas and countries have been well studied, while other areas and countries have been neglected. During the preparation of these volumes, the editors have often been surprised by the wealth of information about some species when little was anticipated, and by the paucity of information about others, some of which were assumed to be 'well known'. In addition to presenting information that is based on sound scientific evidence, the aims of these volumes are to point out where there are gaps in knowledge and to correct inaccurate information that has become embedded in the literature. For most taxa, the detail provided in the species profiles allows accurate identification.

Mammals of Africa comprises six volumes (Table 2). The volumes consist mainly of species profiles – each profile being a detailed

account of the species. They have been edited by six editors who distributed their work according to the orders with which they were most familiar. Each editor chose authors who had extensive knowledge of the species (or higher taxon) and, preferably, had experience with the species in the field. Each volume follows the same general format with respect to arrangement, subheadings and contents. Because *Mammals of Africa* has contributions from 356 authors (each with a different background and speciality), and because each volume was edited by one or more editors (each with a different perspective), it has not been possible or even desirable to ensure exact consistency throughout. Species profiles are not intended to be exhaustive literature reviews, partly for reasons of space. None the less, they are written and edited to be as comprehensive as possible, and to lead the reader to the most important literature for each species. Inevitably, not all information available could be accommodated for the better-known species, and so such profiles are a précis of available knowledge. Extensive references in the text alert the reader to more detailed information.

In addition to the species profiles, there are profiles for the higher taxa (genera, families, orders, etc.). Thus, there is a profile for each order, for each family within the order, for each genus within the family, and for each species within the genus. For some orders there are additional taxonomic levels, for example, tribes (e.g. in Bovidae), subgenera (e.g. in *Procolobus*) and species-groups, or 'superspecies' (e.g. in *Cercopithecus*). The taxonomy used in these volumes mostly follows that presented in the third edition of *Mammal Species of the World: A Geographic and Taxonomic Reference* (Wilson & Reeder 2005), although authors have employed alternative taxonomies when there were good reasons for doing so. Volume I differs from the other volumes in that it contains a number of introductory chapters about Africa and its environment, and about African mammals in general.

The continent of Africa

For the purposes of this work, 'Africa' is defined as the continent of Africa (bounded by the Mediterranean Sea, the Atlantic Ocean, the Indian Ocean, the Red Sea and the Suez Canal) and the islands on the continental shelf, which, at some time in their history, have been joined to the African continent. The largest of the 'continental islands' are Zanzibar (Unguja), Mafia and Bioko (Fernando Po). All 'oceanic islands', e.g. São Tomé, Príncipe, Annobón (Pagulu), Madagascar, Comoros, Seychelles, Mauritius, Socotra, Canaries, Madeira and Cape Verde are excluded, with the exception of Pemba, which is included because of its close proximity (ca. 50 km) to the mainland.

The names of the countries of Africa are taken from the *Times Atlas* (2005). The Republic of Congo is referred to as 'Congo' and the Democratic Republic of Congo (former Zaire) as 'DR Congo'. Smaller geographical or administrative areas within countries are rarely referred to except for Provinces in South Africa, which are used extensively in the literature. Maps showing the political boundaries of Africa (Figure 1a), the Province of South Africa (Figure 1b) and the physical features of Africa with the major rivers and lakes (Figure 1c) are provided, as well as a list of the 47 countries including their previous names that are used in the older literature on African mammals (Table 3).

Africa is the second largest continent in the world (after Asia), but it differs from other continents (except Australia and Antarctica) in being essentially an island. At various times in the past, Africa has been joined to other continents – a situation that has had a strong influence on the fauna and flora of the continent. Africa is a vast continent (29,000,000 km², 11,200,000 mi²) that straddles the Equator, with about two-thirds of its area in the northern hemisphere and one-third in the southern hemisphere. As a result, Africa has many varied climates (with seasons in each hemisphere being six months out of phase), many habitats (including deserts, savannas, woodlands, swamps, rivers, lakes, moist forests, monsoon forests, mountains and glaciers), and altitudes ranging from 155 m (509 ft) below sea level at L. Assal, Djibouti, in the Danakil (Afar) Depression, to 5895 m (19,341 ft) on Mt Kilimanjaro, Tanzania. Africa is comprised of 47 countries, some of which are very large (e.g. Sudan [2,506,000 km²; 967,000 mi²], Algeria [2,382,000 km², 920,000 mi²] and Democratic Republic of Congo [2,345,000 km², 905,000 mi²]), and others that are relatively small (e.g. Djibouti [23,200 km², 9,000 mi²], Swaziland [17,400 km², 6,700 mi²] and The Gambia [11,300 km², 4,400 mi²]). The human population density of each country also varies greatly, from about 346/km² in Rwanda to only about 2.5/km² in Namibia. With its great size and varied habitats, Africa supports a high biodiversity, including a large number of species of mammals. Likewise, most countries have a high diversity of mammals (especially when compared with temperate countries).

Africa may also be divided into biotic zones (Figure 2). A biotic zone is defined as an area within which there is a similar environment (primarily rainfall and temperature) and vegetation, and which differs in these respects from other biotic zones. Thirteen biotic zones are recognized, two of which may be divided into smaller categories. The biotic zones in which each species of mammal has been recorded are listed in each profile for several reasons. They indicate the environmental conditions in which the species lives and they provide data with which the geographic distribution can

Figure 1. (a) Political map of Africa; (b) provinces of South Africa; (c) altitudes and major rivers of Africa. South Sudan and Somaliland are not identified as separate countries in the text.

Table 3. The countries of Africa: names, areas and human population density.

| Country name | Area

Former names are listed in chronological order in square brackets, with the oldest name listed first. Obsolete names are listed because much of the older literature refers to past colonial entities. * = formerly part of French West Africa. # = formerly part of French Equatorial Africa. § At the time of going to press, the country of Sudan had been divided into two: the Republic of Sudan in the north, and the Republic of South Sudan in the south. ‡ The former British Somaliland is now a self-declared state under the name of the Republic of Somaliland, but remains internationally unrecognized.

Figure 2. The biotic zones of Africa.

be explained and predicted. Furthermore, the number of biotic zones exploited by a species indicates its level of habitat tolerance and the extent to which it is vulnerable to loss of a particular type of habitat. The Rainforest Biotic Zone (Figure 3) and the South-West Arid Biotic Zone are divided into regions and sub-regions that reflect the different biogeographical distributions of species, each region/sub-region having a community of mammals and other animals that is different to any other. Details of the Biotic Zones of Africa, and the regions and sub-regions of the Rainforest Biotic Zone and the South-West Arid Biotic Zone, are given in Volume I of *Mammals of Africa*.

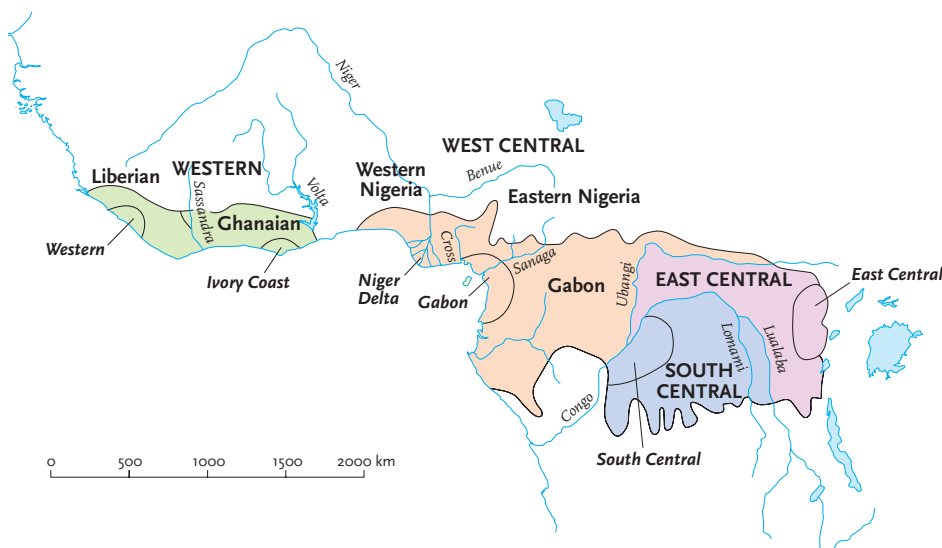

Figure 3. The Rainforest Biotic Zone showing the regions, sub-regions and refugia. Regions are indicated in capital letters and colours: Western region – green; West Central region – brown; East Central region – purple; South Central region – blue. Sub-regions are indicated in lower case letters. Refugia are indicated in lower case italics (after Happold 1996 and references therein; see also Happold & Lock, Volume I, *Mammals of Africa*).

The rodents, hares and rabbits of Africa

This volume, Volume III, is devoted to the orders Rodentia and Lagomorpha. The order Rodentia contains more species (395 spp.) than any other order of African mammals and comprises about 36% of African mammals; in contrast, the order Lagomorpha contains relatively few species (13 spp.). These two orders, together with two orders (Afrosoricida and Macroscelidea) in Volume I and three orders (Erinaceomorpha, Soricomorpha and Chiroptera) in Volume IV, constitute the ‘small mammals of Africa’ and collectively comprise 74.1% (827 of 1116) of all African mammalian species. Many of these small species have not been studied in detail because of their rarity and small geographic ranges. However, some of the more common and widespread species are quite well known, especially with respect to their importance within their communities and because of their importance as ‘bushmeat’ and as hosts for diseases of humans and livestock.

The profiles for Volume III were submitted to the editor between 2001 and 2005. It has not been possible to revise profiles since then except for a few details such as the completion of citations for papers previously given as ‘in press’, alterations (if necessary) to the category of threat in the conservation section of species profiles, and where there have been changes in taxonomy and distribution. An Appendix has been added listing new taxa of African rodents described during the period 2005–2010 and which have not been profiled in this volume.

Species profiles

Information about each species is given under a series of subheadings. The amount of information under each of these subheadings varies greatly between species; where no information is available, this is recorded as ‘No information available’ or words to this effect. The sequence of subheadings and other information is as follows:

Scientific name (genus and species) The currently accepted name of the species.

Vernacular Names English, French and German names are given, as available. The first given English name is the preferred vernacular name for the species; alternative names are given in parentheses for some species. Wilson & Cole (2000) list proposed vernacular names for all the world's mammals; most of these names were also given in the third edition of *Mammal Species of the World* (Wilson & Reeder 2005). Although these works have been consulted, the names used have not always been adopted in *Mammals of Africa*. In Volume III, French names were either provided by authors, or taken from Gunther (2002); most of the German names were provided by Anke Hoffman.

Scientific Citation This provides the full scientific name of the species, i.e. genus name, species name, authority name and date of authority. Parentheses around the authority's name and date indicate that the species was originally named in a different genus to the one it is placed in now. The scientific name is followed by the publication in which the species was described, and the type locality (i.e. where the type specimen [or type series] was obtained). Most of this information is taken from Wilson & Reeder (2005).

Taxonomy This section contains information about previous scientific names of the species, and problems and controversies (if any) associated with its nomenclature and relationships with other species. For some species, there is considerable information about these topics; for others, there may be nothing. Synonyms are listed in alphabetical order (without the taxonomic authority for each unless essential for clarity) and the number of subspecies (if any) is presented; most of this information is taken from Wilson & Reeder (2005). The chromosome number is given if available, and in some cases this is followed by other information relevant to the chromosomes. In late 2006, a revised edition of the *Atlas of Mammalian Chromosomes* was published (O'Brien *et al.* 2006), but it has not been possible to incorporate the findings of that important work here.

Description This section, together with the illustrations and relevant tables, provides sufficient information to identify the species as well as describing characters that are relevant to the habits and lifestyle of the species. The section begins with a brief overall description of the species, including an indication of size. This is followed by a detailed description of the external characters of the species – head (and parts of the head), dorsal pelage, legs, feet, ventral pelage, and tail (in this order), as well as any special characteristics unique to the species. For some species, diagnostic characteristics of the skull are given. The characters described in this section are common to all subspecies (if any) of the species (see also Geographic Variation). It was not possible – or desirable – to describe the same suite of characters for every species. Instead, an appropriate selection was made for each family and/or genus, and therefore the same suite of characters is described for all members of the relevant taxon. Consequently the descriptions of related species are comparable and compatible. Characters that are diagnostic to the genus are not necessarily repeated in a species profile; hence higher taxa profiles should also be consulted. The number and arrangement of nipples in adult females is noted wherever this feature varies between the taxa being discussed (see Glossary). The Tables allow easy comparison between taxa within a genus or family.

Geographic Variation Variation within the species may be of two sorts: (a) clinal variation without subspecies, or (b) subspecific variation. If (a), there is a description of the character(s) that alter clinally across the geographic range of the species. If (b), each of the subspecies is listed with its geographic range and the characters that distinguish it from other subspecies of the species.

Similar Species Species that are sympatric or parapatric with the species under consideration, and with which it may be confused, are listed along with diagnostic characteristics (additionally, readers may

External characters of a hypothetical rodent. No species has this particular combination of characters.

External characters of a hypothetical lagomorph.

refer to profiles of the similar species in question). In some instances, similar species that are allopatric in distribution are also included.

Distribution The first sentence, 'Endemic to Africa', if given, indicates that this is an African species and does not occur in the wild on any other continent; if a species also occurs outside Africa (and hence is not endemic), this is noted at the end of this section. The next sentence gives the Biotic Zone (or Zones) in which the species has been recorded because this information indicates the sorts of environments exploited by that species, its tolerance of different environmental conditions, and the extent to which it is likely to be threatened by habitat change. Also, it is the basis for predictions of its distribution outside the currently known limits. Finally, the countries (or parts of countries) where the species has been recorded are listed; sometimes other data (such as altitudinal range and habitat) are also included. As a general rule, descriptions of the geographic range for species with very restricted distributions are more precise in terms of information given (including, for example, geographic coordinates) than for more widespread species, where a more generalized statement is adequate. A distribution map (see below) augments the information given here.

Habitat This section provides a description of the habitat, or range of habitats, where the species lives. Details of plant communities, plant species, vegetation structure, soil type and/or structure and water availability, etc. (if available) are also recorded. Other information may include average annual rainfall, altitudinal limits and seasonal variations in habitat characteristics.

Abundance This section attempts to indicate the comparative abundance of the species in its habitat. For many species, quantitative data are unavailable but the species can be assessed as 'abundant',

'common', 'uncommon', 'rare', 'rarely seen but frequently heard', 'rarely collected' etc. For some species, abundance may be expressed as estimates of density (e.g. number/ha or number/km²), or relative abundance within the community (e.g. 'comprised 40% of small mammals captured', 'the second most numerous species'). For the better-known or rare species, actual numbers of individuals for the species may be given. Other information may include seasonal changes in density, frequency of observations, or the relative abundance of specimens in collections.

Adaptations This section describes morphological, physiological and behavioural characteristics that show how the species uniquely interacts with its environment, with conspecifics, and with other animals. This section may also describe species-specific adaptations for feeding, locomotion, burrowing, domiciles, mechanisms for orientation, production of sound, sensory mechanisms and activity patterns. In some instances, comparison with related or convergent species allows the unique adaptations of the species under discussion to be detailed or emphasized.

Foraging and Food The first sentence briefly describes the diet of the species (e.g. insectivorous, carnivorous, granivorous, etc.). This may be followed by the methods of collecting food (foraging), size of home-range and daily distance moved, and descriptions of feeding behaviour. The diet, if well-known, is then described in one or more of the following ways: a list of the taxa of animals or plants consumed, a quantitative measure based on direct observations, or by a qualitative or quantitative analysis of the stomach contents or faeces.

Social and Reproductive Behaviour Topics in this section may include social organizations (e.g. solitary, social, or colonial), group

size and composition; agonistic and amicable behaviour, territoriality and home-range (including quantitative data), courtship and mating, parental behaviour, and parent–young interactions, cooperative breeding, social vocalizations, and interactions with other species (mammals, birds, etc.).

Reproduction and Population Structure This section begins with an assessment of reproductive strategy (if known) and the times/seasons of the year when individuals are reproductively active (pregnancy and lactation in females, active spermatogenesis in males). Other information may include length of gestation, times/seasons of births, including peaks of births, litter-size, birth-weight and size, spacing of litters, growth and time to weaning, maturity, longevity, and mortality rates. Reproductive chronologies, if known, give data for both individuals and local populations. Reproductive strategies, if known, are described with respect to locality, food availability and population density. Population structure (sex ratio, adult/young ratio, abundance of different cohorts in the population at different times of the year) may be described, and related to seasonal variations in reproduction and environmental variables.

Predators, Parasites and Diseases The known predators, known parasites (usually ectoparasites only) and some diseases are listed. Additional information is given if the species is a host to diseases that affect humans and domestic stock, and if it is utilized as food for humans ('bushmeat').

Remarks This subheading subsumes five of the above subheadings (Adaptations, Foraging and Food, Social and Reproductive Behaviour, Reproduction and Population Structure, and Predators, Parasites and Diseases) in those instances where there is little or no information available.

Conservation The conservation status of the species (i.e. its IUCN Category) is taken from the 'Red List of Threatened Species' prepared by the International Union for Conservation of Nature (IUCN). The IUCN Red List Categories follow the definitions given in the *IUCN Red List Categories and Criteria Version 3.1* (see www.iucnredlist.org) and are listed in Table 4. For those species that are classified as threatened (i.e. 'Vulnerable', 'Endangered' and 'Critically Endangered'), readers may obtain detailed reasons (the criteria) for the classification on the IUCN Red List website. The status of some species has been changed in recent years because of improved knowledge, changes in taxonomy, or the impact of threatening processes or conservation action; detailed reasons for the present status, and past status, are given on the IUCN Red List website. If a species is listed on an Appendix I or Appendix II under CITES (Convention on International Trade in Endangered Species; www.cites.org), this is also indicated. For some species, additional information is provided, such as presence in protected areas, major threats, and current or recommended conservation measures.

Measurements A series of morphological measurements is provided. For each species there is a standard set of measurements. The abbreviation and definition for each measurement is given in the Glossary. A measurement is cited as the mean value (with minimum value to maximum value in parentheses) and sample size. For some, the standard deviation (mean \pm 1 S.D.) is given instead of the range. For most measurements, data for males and females are combined but where there is sexual dimorphism, measurements for males and females are given separately. Where possible, measurements also detail the location(s) where the specimens were obtained, and the source of the data. Sources are either cited publications, or specimens in museums, or unpublished information from authors or others. The acronyms for museums where specimens were examined

Table 4. Definitions for the IUCN Red List categories (from IUCN – Red List Categories, Version 3.1).

| Category | Description |
|-----------------------------------|--|
| Extinct (EX) | A taxon is Extinct when there is no reasonable doubt that the last individual has died. A taxon is presumed Extinct when exhaustive surveys in known and/or expected habitat, at appropriate times (diurnal, seasonal, annual), throughout its historic range have failed to record an individual. Surveys should be over a time frame appropriate to the taxon's life-cycles and life form. |
| Extinct in the Wild (EW) | A taxon is Extinct in the Wild when it is known only to survive in cultivation, in captivity or as a naturalized population (or populations) well outside the past range. A taxon is presumed Extinct in the Wild when exhaustive surveys in known and/or expected habitat, at appropriate times (diurnal, seasonal, annual), throughout its historic range have failed to record an individual. Surveys should be over a time frame appropriate to the taxon's life-cycle and life-form. |
| Critically Endangered (CR) | A taxon is Critically Endangered when the best available evidence indicates that it meets any of the criteria A to E for Critically Endangered, and it is therefore considered to be facing an extremely high risk of extinction in the wild. |
| Endangered (EN) | A taxon is Endangered when the best available evidence indicates that it meets any of the criteria A to E for Endangered, and it is therefore considered to be facing a very high risk of extinction in the wild. |
| Vulnerable (VU) | A taxon is Vulnerable when the best available evidence indicates that it meets any of the criteria A to E for Vulnerable, and it is therefore considered to be facing a high risk of extinction in the wild. |
| Near Threatened (NT) | A taxon is Near Threatened when it has been evaluated against the criteria but does not qualify for Critically Endangered, Endangered or Vulnerable now, but is close to qualifying for (or is likely to qualify for) a threatened category in the near future. |
| Least Concern (LC) | A taxon is Least Concern when it has been evaluated against the criteria and does not qualify for the Critically Endangered, Endangered, Vulnerable or Near Threatened categories. Widespread and abundant taxa are included in this category. |
| Data Deficient (DD) | A taxon is Data Deficient when there is inadequate information to make a direct, or indirect, assessment of its risk of extinction based on its distribution and/or population status. Data Deficient is not a category of threat. Listing of taxa in this category indicates that more information is required and acknowledges the possibility that future research will show that a threatened classification is appropriate. |
| Not Evaluated (NE) | A taxon is Not Evaluated when it has not yet been evaluated against the criteria. |

and measured are given in Table 5. Most museum records have been provided by the author of the profile; others – when an author did not have the measurements or did not have the opportunity to visit museums – were provided by the editor.

Key References A select list of references, which provides more general information on the species. Each reference is given in full in the Bibliography.

Author The name of the author, or authors, is given at the end of each profile. All profiles should be cited using the author name(s).

Tables For selected taxa (mainly families and genera) tables provide details of the main characteristics of these taxa and can be used as an aid to identification. The tables were prepared by the editor.

Higher taxon profiles

The profiles for orders, families and genera are less structured than for the species. Each profile usually begins with a listing of the taxa in the next lower taxon; for example, each family profile lists the genera in that family. An exception to this arrangement is where a

taxon has only one lower taxon. Higher taxa profiles provide the characteristics common to all members of that taxon. Some of these characteristics may not be repeated in lower taxon profiles (unless essential for identification) so readers are encouraged to consult also the next higher taxon profile, e.g. the species profile for *Lophuromys sikapusi* should be consulted in association with the genus *Lophuromys* profile.

Distribution maps

Each species profile, with very few exceptions, contains a pan-African map showing the geographic range of the species. Most maps were provided by the author of the profile and were compiled from literature records and museum specimens; some maps were provided by the editor(s) when it was not possible for the author to do so. Each map shows the boundaries of the 47 countries of Africa, some of the major rivers (Nile, Niger–Benue, Congo [with the tributaries Ubangi, Lualaba and Lomani], Zambezi and Orange), and Lakes Chad, Tana, Turkana (formerly Rudolf), Albert, Edward, Victoria, Kyoga, Kivu, Tanganyika, Malawi, Mweru, Bangwuela and Kariba. The map projection is ‘Transverse Mercator, with the following parameters: False Easting: 0; False Northing: 0; Central Meridian: 20; Linear Unit: metre; Datum: Clarke 1866’.

The geographic distribution of a species is indicated as:

- red shading = current range(s). When presented, different colour shading denotes subspecies.
- × = isolated locations considered to be separate from the main geographic range(s). Some locations indicated by × may include two or more closely spaced locations.
- ? = locality of uncertain validity; relevant information usually in text.
- red arrow = present on the island indicated by the arrow.

Distribution and diversity

Rodentia is the largest order of Mammalia, encompassing 2,277 of 5,422 living mammal species or approximately 42% of worldwide mammalian biodiversity (Wilson & Reeder 2005); of these 2,277 rodent species, 395 species (in 15 families and 98 genera) occur in Africa (see above and Table 1). Rodents are indigenous to every continent except Antarctica and inhabit most small to large land-bridge and oceanic islands (originally absent from Iceland, New Zealand and some oceanic and high Arctic islands). The order's global presence has become nearly ubiquitous as certain commensal species (see subfamily Murinae profile) have expanded their ranges in concert with human peregrinations during the Holocene. Large islands, island archipelagos and those continents with a geologic history of periodic isolation, have afforded ideal geographic settings for *in situ* radiations of major clades of Rodentia. Nowhere, with the arguable exception of South America, is this cladogenetic exuberance of the order so spectacularly showcased as in Africa, where 14 of the 33 recognized rodent families (*sensu* Wilson & Reeder 2005) are indigenous; a 15th family, Myocastoridae, has been introduced into Africa (Table 6). Seven of these 15 families are endemic to the continent (Table 6); at the generic and specific levels, the extent of endemism is substantially greater and highlights the contribution of African landscapes to the phylogenetic diversification of these rodent families (Table 1). Most non-endemic genera and species involve North African taxa that range into the nearby Arabian Peninsula and

Table 6. The 15 families of recent African Rodentia, with the number of constituent genera and species. Percentage endemism is based on the geographic limits of the African continent as defined for this volume and on the taxa recognized herein.

| Family | Endemic | No. of genera | No. of endemic genera | No. of species | No. of endemic species |

Figure 4. The number of taxa of African rodents. Green line: cumulative number of species-group taxa (species and subspecies) described from Linnaeus (ca. 1750) to the year 2003 (total = 1729); principal authors and the span of their scientific contributions (dotted lines) are indicated, with the number of African taxa they described in parentheses. Red line: number of species considered scientifically valid (line fitted visually); red dots indicate species numbers recognised by Murray (1866), Trouessart (1897–98), Allen (1939), Ellerman (1940–41), Corbet & Hill (1980, 1991), Wilson & Reeder (1993, 2005). (From original by M. D. Carleton.)

Middle East; generic and specific endemism is nearly 100% within sub-Saharan zones, where taxa tend to be more narrowly restricted in distribution and limited to distinct sub-regions (e.g. Coe & Skinner 1993, Happold 1996).

The magnitude of species endemism within Africa, albeit nearly 95% (Table 6), surely remains an underestimate, for the number of rodent species considered to be valid has continued to increase in the last quarter-century (Figure 4). Knowledge of the diversity of African rodents initially grew slowly in the post-Linnaean discovery phase (ca. 1800–1860s). However, an exceptionally fertile period of natural history exploration and taxonomic description commenced in the late 1800s, during which the subspecies emerged as a standard rank to formally identify intra-specific variation. Oldfield Thomas of the British Museum of Natural History was a prodigious worker and influential systematist throughout this eruptive phase of taxonomic description (ca. 1880–1930s). By the conclusion of this era, more than 600 species of African rodents were recognized (Allen 1939). During the middle 1900s (ca. 1940–1970s), the number of species considered to be valid dipped to less than 300 (Corbet & Hill 1980), a decrease driven by widespread acceptance of the biological species concept and its taxonomic application as intergrading geographic races (subspecies). New subspecies continued to be named at a high rate, and many species described during the preceding eruptive phase were cursorily demoted to subspecies. The last subspecies of African Rodentia were named in 1983. The revived appreciation of greater species richness, as witnessed in the past two decades, has been impelled by new field discoveries, by reinvigorated museum-based revision and by improved methodologies for evaluating and taxonomically interpreting inter-population differences, be they morphological, chromosomal, or molecular. Thus, the approximately 400 species covered herein are a tenuous summary of an animated study in progress, whose outcome over the next 10–15 years is likely to stabilize the number of African rodents at about 500 species (Figure 4).

Coupled with its species richness, the Rodentia is remarkable for its morphological diversity, and essentially every ecological, behavioural, trophic and locomotory adaptive theme that has evolved within the order is represented among the African taxa (see familial and generic accounts).

Morphological definition and incisor function

Notwithstanding the protean morphological variety exhibited by rodents, the order is well defined in combination by several derived characters or functionally related character complexes. The upper and lower jaws each bear a single pair of enlarged and ever-growing chisel-like incisors that ontogenetically represent retained deciduous second incisors ($i^{2/2}$ – Luckett 1985); the incisor enamel is mainly limited to the anterior surface and is two-layered, the inner layer of which is composed of hydroxyapatite crystal prisms arranged in characteristic decussating patterns (Martin 1993, 1999). The dentition consists of a maximum of 22 teeth (incisors $1/1$, canines $0/0$, premolars $2/1$, molars $3/3$) as documented in the earliest of fossil species currently recognized as rodents. The upper and lower molars are quadritubercular, the uppers possessing a longitudinal enamel connection (mure) between the protocone and hypocone and the lowers lacking a paraconid (Meng *et al.* 2003, Marivaux *et al.* 2004). The glenoid fossa is elongate, lacking pre- and postglenoid processes, and enables the free anterior–posterior excursion of the mandible into effective occlusion for gnawing (incisors) or chewing (cheekteeth). A conspicuous diastema is present between the anterior incisors and posterior cheekteeth due to loss of the first and last incisors, canines and anterior premolars; the upper diastema is significantly longer than the lower. With formation of a diastema, fur-covered labial infoldings occur behind the incisors to partially segregate gnawing from chewing activity. The masticatory muscles

are complexly subdivided, the masseteric series being massive in size and volume relative to the temporalis; a discrete superficial masseter is always present. In primitive rodents, all masseter muscles originate from the zygomatic arch, and the infraorbital foramen is small, serving as passage only for nerves and blood vessels (protrogomorphous). In derived rodents, different masseteric bundles extend anteriorly either onto an expansive zygomatic plate (sciurumorphous), through a greatly enlarged infraorbital foramen onto the lateral rostrum (hystricomorphous), or onto both in combination (myomorphous). The latter three zygomaseteric morphologies are represented among living African Rodentia (Figure 5) and have figured prominently as characters in its subordinal classification (see below). The auditory bulla is composed entirely of the ectotympanic bone. The literature on rodent morphology is extensive: see Tullberg (1899), Ellerman (1940) and Carleton (1984) for additional morphological characterization of Rodentia; see Hartenberger (1985), Luckett (1985), Luckett & Hartenberger (1993), Landry (1999) and Meng *et al.* (2003) for phylogenetic commentary on the preceding traits and others as ordinal synapomorphies, particularly as compared with Lagomorpha.

The enlarged incisor teeth, reduced to a single pair each at the front of the upper and lower jaws, represent a key evolutionary innovation (*sensu* Brooks & McLennan 1991) that plausibly fostered the remarkable success of the order, which typically constitutes the most species-rich clade of Mammalia found in the fossil record since its initial radiation in the early to middle Eocene (40–55 mya). That success owes much to the intrinsic biomechanical properties of the continually erupting incisors and their consequent effectiveness as a multipurpose tool. The differential hardness of the enamel and dentine, together with microstructural specializations of the enamel layers, allow formation of an acute edge. Hydroxyapatite crystal prisms of the inner enamel layer are arranged in intricately interwoven patterns (pauciserial in early rodents, multiserial and uniserial in derived lineages – Martin 1993); these further reinforce the working bevel of the incisors and inhibit propagation of cracks along the relatively brittle and thin enamel sheath during conditions of intense activity and when strong forces are concentrated on the narrow tips (von Koenigswald 1985, Martin 1993). Ultimately, the keen sharpness and chisel shape of the incisors are achieved by deliberate honing motions of the lower incisors upon the upper incisors, not as a coincidental result of wear (von Koenigswald 1985, Druzinsky 1995). Indeed, some researchers consider the chisel shape of the rodent lower incisor and its intentional maintenance as a cardinal morphological-behavioural synapomorphy of the order (Landry 1999, Meng *et al.* 2003).

The adaptive role of the incisors is usually described as ‘gnawing’, but that term inadequately captures the range and multiplicity of their uses. Biting and cutting, piercing and stabbing, holding and seizing, tearing and slicing, gouging and scraping (digging), chipping and prising, interdental sharpening and chattering, gathering and carrying of foodstuffs or nesting material, carrying of young by parents and teat-clinging by neonates, are other functions observed within species and across the order (Lawrence 1941, Landry 1970, Offermans & DeVree 1990, Druzinsky 1995, van der Merwe & Botha 1998). Most of the functions of the incisors involve feeding and food habits and reflect the diverse trophic niches and dietary flexibility that are hallmarks of Rodentia (Landry 1970); other functions relate to aspects of communication, behaviour, ecology and reproduction. The exceptional mobility of the mandible, so integral to a rodent’s

livelihood, was evolutionarily realized through extensive reorientation of the jaw muscles and concomitant remodelling of the head skeleton. Although these adaptations originally appeared to protrude the mandible for incisor occlusion and to strengthen incisal cutting (Meng *et al.* 2003), they coincidentally preadapted the masticatory apparatus for subsequent evolution of molar hypsodonty, planar occlusal surfaces and propalinal chewing suited to triturating high-fibre plant material, notably grasses (Landry 1999, Mess *et al.* 2001). Expanding reliance upon herbivorous resources has characterized several rodent lineages that independently radiated in concert with the development of open environments in the Oligocene and proliferation of grasslands in the Miocene (Jacobs *et al.* 1999, Mess *et al.* 2001).

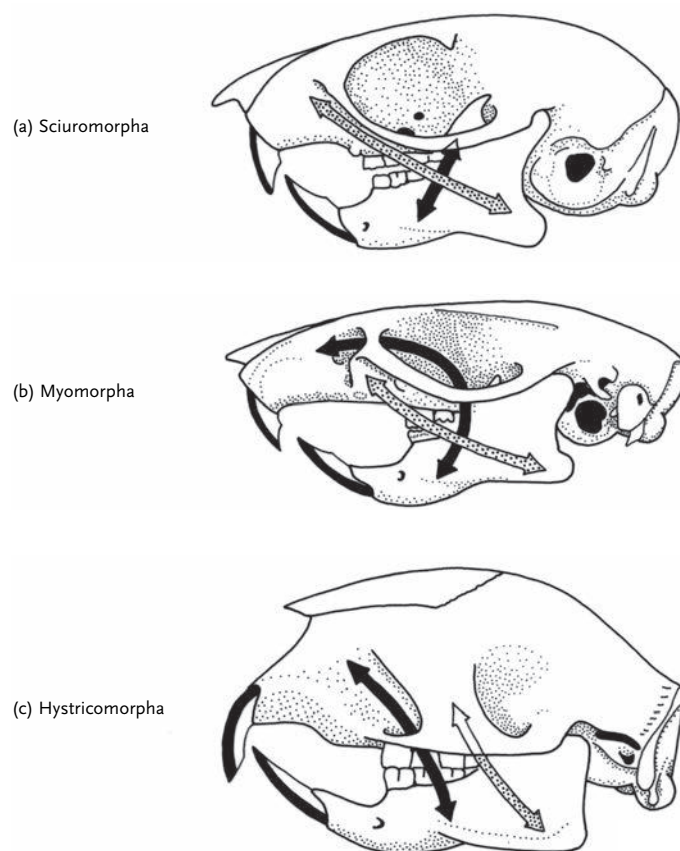

Figure 5. Orientation of jaw musculature in the three suborders of African Rodentia. Stippled arrow = masseter lateralis muscle (= middle masseter). Black arrow = masseter medialis muscle (= deep masseter). Clear arrow = muscle attached to inner surface of zygomatic arch.

(a) Sciuromorpha: masseter lateralis originates on outer side of skull in front of orbit (zygomatic plate) and inserts on posterior part of mandible, and masseter medialis originates on the inner surface of the zygomatic arch and inserts on the middle part of the mandible. Infraorbital foramen is very small; no part of the masseter muscle passes through the foramen.
(b) Myomorpha: masseter lateralis is similar to that of Sciuromorpha but the masseter medialis has pushed up through the orbit and through the enlarged infraorbital foramen so its origin is on the rostrum.
(c) Hystricomorpha: masseter lateralis retains the primitive position originating on the inner surface of the zygomatic arch and inserts on the mandible, and the masseter medialis has its origin more anteriorly on the mandible and passes through the enlarged infraorbital foramen and inserts on the rostrum. Other jaw muscles (superficial masseter muscle and temporalis muscles), which are similar in all suborders, are not shown. The area of muscle attachment to the underlying bone is more extensive than the arrows indicate (after Romer 1966).

Phylogeny and classification

Such morphological traits have long encouraged the view that living rodents are derived from a common ancestor, as conveyed in numerous classifications of Rodentia from Brandt (1855) to Landry (1999). Taxonomically broad, cladistic studies of morphological characters have sustained the historical view of Rodentia as a monophyletic group (Novacek 1985, Novacek & Wyss 1986, Luckett & Hartenberger 1993, Shoshani & McKenna 1998, Meng *et al.* 2003). Although some early gene-sequencing studies implied, or concluded, that hystricognath rodents (*Cavia* and relatives) represent a separate mammalian order and that Rodentia as conventionally classified is polyphyletic (Graur *et al.* 1991, 1992, D'Erchia *et al.* 1996), the ensuing wave of molecular research, based on wider sampling of taxa (particularly the in-group Rodentia) and genes, has decisively solidified the case for rodent monophyly (Huchon *et al.* 1999, 2002, Robinson-Rechavi *et al.* 2000, Adkins *et al.* 2001, 2003, Debry & Sagel 2001, Lin *et al.* 2002, Armine-Madsen *et al.* 2003, Debry 2003, Waddell & Shelley 2003, Reyes *et al.* 2004).

Recognition of major lines of descent within Rodentia and their formal classification, usually at the rank of suborders, historically has provoked more contention than the question of monophyly of the order.

The two prevalent classificatory schemes stem from Brandt (1855) and Tullberg (1899): Brandt's tri-subordinal division emphasized zygomaseteric morphology (sciuromorphy, hystricomorphy and myomorphy); and Tullberg's dual subordinal arrangement integrated mandibular conformation (sciurognathy versus hystricognathy) with zygomaseteric criteria (Table 7). Subsequently, most systematists have adopted or elaborated either Brandt's (Alston 1876, Simpson 1945, Wood 1965) or Tullberg's subordinal taxonomies (Ellerman 1940, Chaline & Mein 1979, Landry 1999). Other classifications have recognized anywhere from five to 16 major phyletic divisions within Rodentia, whether or not called a suborder *per se* (Thomas 1897, Miller & Gidley 1918, Wood 1955, Thaler 1966, Hartenberger 1985, 1998, McKenna & Bell 1997, Carleton & Musser 2005). In spite of these classificatory disagreements at the level of suborder, certain phyletic affinities among the 33 recognized families have consistently emerged based on morphological and gene-sequencing evidence published over the past decade. Although ranks between family and order are not considered in this volume, the following four kinship-groups are apparent among the 14 rodent families that occur in Africa. Morphological characters, evidence for monophyly, and fossil history of individual families are covered in the respective family introduction.

Table 7. Taxonomic placement and presumed higher-level relationships among 14 African families as interpreted in past influential classifications of Rodentia.^a

^aThose African families in brackets were not specifically recognized in a given classification, but their genera belong to the family listed above.

^bIn early classifications, such as Alston (1876) and Thomas (1897), *Petromus*, *Thryonomys* and the ctenodactylid genera were grouped with the Octodontidae of South America. Subsequent research, beginning with Tullberg (1899), has indicated that these African families constitute distinct families endemic to Africa and that they are only distantly related to the octodont rodents of South America.

(1) *Sciuridae + Gliridae (= Sciuriomorpha)*

Sciurid rodents possess a sciurognathus mandible and sciuriomorphous masseteric condition and have composed the core of Brandt's (1855) Sciuriomorpha, as reflected in classifications generated from the late 1800s to the present (e.g. Alston 1876, Thomas 1897, Simpson 1945, McKenna & Bell 1997). Union of Sciuridae with Gliridae (dormice) in an expanded clade, however, recently has garnered additional evidence. The zygomaseteric structure of extant glirids (excepting African *Graphiurus*) was widely interpreted as myomorphous, and so influenced systematists to associate dormice with Myomorpha (Alston 1876, Thomas 1897, Ellerman 1940, Chaline & Mein 1979, Wahlert *et al.* 1993). However, the 'myomorphy' observed in most living dormice is now understood to be convergent to the zygomaseteric configuration in Myomorpha proper and has been termed 'pseudomyomorphy' (Vianey-Liaud 1985, Maier *et al.* 2002). The deep and rich fossil record of Gliridae implies their derivation in the very early Eocene from protrogomorphous ischyromyids (Vianey-Liaud 1985, 1994, Hartenberger 1994, 1998), the same fossil group also known to be ancestral to Sciuridae (and North American Aplodontidae). In agreement with the palaeontological interpretation, analyses of both mitochondrial and nuclear genes disclose Gliridae as sister-group to Sciuridae or to a sciurid-aplodontid clade (Kramarov *et al.* 1999, Huchon *et al.* 1999, 2002, Adkins *et al.* 2001, 2003, Debry & Sagel 2001, Montgelard *et al.* 2002, Reyes *et al.* 2004).

(2) *Dipodoidea [Dipodidae] + Muroidea [Spalacidae–Nesomyidae–Cricetidae–Muridae] (= Myomorpha)*

Common ancestry of the Dipodoidea and Muroidea has long been recognized, notably as first depicted by Tullberg (1899). Their close phyletic union has been sustained by substantial palaeontological data (Wilson 1949, Emry 1981, Walsh 1997, Emry *et al.* 1998) and morphological systems, such as molar occlusal patterns and loss of the lower fourth premolar (Flynn *et al.* 1985, Marivaux *et al.* 2004), cephalic arterial plans (Bugge 1985) and foetal membrane traits (Luckett 1985). Although extant dipodoids (hystricomorphous) and muroids (myomorphous) differ in their zygomaseteric construction, extinct cricetids of the late Eocene and early Oligocene possessed a hystricomorphous infraorbital condition (Flynn *et al.* 1985, Vianey-Liaud 1985); fossils with intermediate zygomaseteric structures, along with plausible myological transformations (Klingener 1964), endorse the derivation of myomorphy from an hystricomorphous ancestor. Such a conclusion is further implicit in molecular studies of broad taxonomic scope (Nedbal *et al.* 1996, Adkins *et al.* 2001, 2003, Debry & Sagel 2001, Michaux *et al.* 2001, Jansa & Weksler 2004). Schaub (1958) formally identified the cognate relationship of Dipodoidea and Muroidea as the infraorder Myodonta, within the suborder Myomorpha, a classification also recognized by McKenna & Bell (1997).

(3) *Anomaluridae + Pedetidae (= Anomaluromorpha)*

Scaly-tailed squirrels (*Anomaluridae*) and springhares (*Pedetidae*) are characterized by a hystricomorphous skull and sciurognathus mandible, an unusual combination of traits that has confused their clear-cut assignment to the traditional suborders. Some systematists have treated one or both families as *incertae sedis* within Rodentia (e.g. Simpson 1945, Wood 1965, Chaline & Mein 1979, Hartenberger

1998). Others have arranged the two groups in the same superfamily or suborder (Winge 1887, Tullberg 1899, McKenna & Bell 1997), and this kinship has drawn support based on arterial patterns (Bugge 1974b, George 1981c), middle ear anatomy (Lavocat & Parent 1985, Meng 1990) and mitochondrial genes (Montgelard *et al.* 2001, 2002). Some investigators dispute any special relationship between *Anomaluridae* and *Pedetidae* (e.g. Jaeger 1988a, Hartenberger 1998, Landry 1999), especially given fundamental microstructural differences in their incisor enamel (Martin 1993, 1995). These authors would independently derive *Anomaluridae* from certain Eocene families (Martin 1993, Hartenberger 1998) or ally it as a sister-group with *Sciuridae* (Landry 1999), and tentatively affiliate *Pedetidae* with the *Ctenodactylidae*–*Hystricognathi* clade (George 1985b, Martin 1995, Landry 1999). The phylogenetic issues surrounding *Anomaluridae* and *Pedetidae* and their suprafamilial classification continue to invite resolution.

(4) *Ctenodactylidae + Hystricognathi [Bathyergidae, Hystricidae, Petromuridae, Thryonomyidae] (= Hystricomorpha)*

The African gundis, *Ctenodactylidae*, represent another group whose phylogenetic placement has perplexed systematists. The family was early placed in *Hystricomorpha* (Alston 1876, Thomas 1897), but later arranged within *Sciurognathi* (Ellerman 1940, Chaline & Mein 1979), isolated (among living families) in its own suborder, *Sciuravida* (McKenna & Bell 1997), or left as a suborder or infraorder *incertae sedis* (Simpson 1945, Wood 1955, 1965). A jointly impressive body of research supports association of ctenodactylids with *Hystricomorpha sensu lato*. Such corroborative studies broadly draw upon morphology, both individual character systems and multicharacter cladistic analyses (Landry 1957, 1999, Bugge 1985, George 1985b, Lavocat & Parent 1985, Meng 1990, Martin 1994, 1995, Bryant & McKenna 1995), palaeontology (Flynn *et al.* 1986, Marivaux *et al.* 2002, 2004, Marivaux & Welcomme 2003) and DNA sequences (Huchon *et al.* 2000, 2002, Adkins *et al.* 2001, 2003, Huchon & Douzery 2001, Montgelard *et al.* 2002, Jenkins *et al.* 2005). Since Tullberg's (1899) seminal monograph, the four African families that possess hystricomorphous jaw musculature and a hystricognathus mandible (*Bathyergidae*, *Hystricidae*, *Petromuridae*, *Thryonomyidae*) have been viewed as closely related to one another and to those in the New World. Subsequent research has ratified his arrangement in the broad sense (see summaries in Luckett & Hartenberger 1985, Landry 1999, Jenkins *et al.* 2005). Whether the Palaeotropical families (*Phiomorpha sensu* Lavocat 1971) and Neotropical families (*Caviomorpha sensu* Wood & Patterson 1959) represent monophyletic radiations within *Hystricognathi* remains uncertain, although some recent investigations support such an interpretation (Nedbal *et al.* 1994, Huchon & Douzery 2001, Marivaux *et al.* 2004).

Rodents have long been accepted as most closely related to hares and rabbits. The two groups were initially arranged as the suborders *Simplicidentata* (rodents) and *Duplicidentata* (hares and rabbits) in the order Rodentia or Glires (e.g. Alston 1876, Thomas 1897, Gregory 1910) and later placed in separate orders, Rodentia and Lagomorpha, within the cohort Glires (Gidley 1912, Simpson 1945, Landry 1999). Surprisingly, a persuasive palaeontological foundation for their cognate relationship did not emerge until the late 1900s (Li *et al.* 1987, Li & Ting 1993, Dashzeveg *et al.* 1998). With increased knowledge of these extinct groups (*Mimotonidae*, *Eurymylidae* and others), relationships

among basal Glires and their classification have become correspondingly complex (see Meng *et al.* 2003). Notwithstanding the phylogenetic intricacies involving extinct gliriform mammals, common ancestry of the orders Lagomorpha and Rodentia among living mammals is decisively sustained in modern phylogenetic studies (for morphological evidence, see Novacek & Wyss 1986, Novacek *et al.* 1988, Lockett & Hartenberger 1993, Shoshani & McKenna 1998, Martin 1999, Meng & Wyss 2001, Meng *et al.* 2003; for molecular evidence, see Eizirik *et al.* 2001, Murphy *et al.* 2001, Huchon *et al.* 2002, Lin *et al.* 2002, Armine-Madsen *et al.* 2003, Waddell & Shelley 2003). The clade Rodentia–Lagomorpha is distantly related to Primates, Dermoptera (colugos) and Scandentia (tree shrews), a phyletic association of five orders now recognized as the superorder Euarchontoglires (Murphy *et al.* 2001, Scally *et al.* 2001, Huchon *et al.* 2002, Lin *et al.* 2002, Helgen 2003, Waddell & Shelley 2003, Reyes *et al.* 2004).

Geologic age and continental areas of origin

The oldest rodents represent several ischyromyid genera (Sciuromorpha) from the late Palaeocene of North America, and these or related forms are documented in the early Eocene of Asia and Europe (McKenna & Bell 1997, Hartenberger 1998). The explosive diversification of Rodentia into principal lineages (suborders) occurred during the early to middle Eocene, and examples of most modern families are encountered by the middle to late Oligocene (Wood 1959, Hartenberger 1996, 1998). In Africa, the earliest rodents so far recorded appear in the early Eocene, including forms (Zegdomyidae) considered to be ancestral to living Anomaluridae (Vianey-Liaud *et al.* 1994), and in the late Eocene–early Oligocene, including forms (Phiomyidae) related to African Hystricognathi, in particular Thryonomyidae (Wood 1968, Lavocat 1978, Jaeger *et al.* 1985). These Eocene and Oligocene records originate from sites in the Sahara and along the Mediterranean rim of North-West Africa. The first geologic appearances of most African rodent families, including the largest groups (Sciuridae, Gliridae, Nesomyidae, Muridae, Bathyergidae), date from the middle to late Miocene, the majority as recorded from sub-Saharan countries (Table 8). Based on the oldest fossils so far discovered and their cladistically basal stature within Glires or Rodentia, Asia is presently accepted as the continental area of origin for the order (Bryant & McKenna 1995, Dawson & Beard 1996, Hartenberger 1996, Beard 1998, Meng & Wyss 2001).

African rodent groups are generally thought to be derived from southern Asian progenitors, some time during the middle to late Miocene, and they presumably reached Africa by immigration through the Arabian Peninsula into East Africa and along the Mediterranean into North Africa. The timing and direction of faunal interchange are based on intercontinental comparisons of earliest fossil dates (Lavocat 1978, Jacobs 1985, Wang 1994, Winkler 1994, Flynn & Jacobs 1999) and on cladistic biogeography as inferred from phylogenetic studies (Huchon & Douzery 2001, Mercer & Roth 2003). Such a biogeographic origin and dispersion chronology convincingly account for certain families that occur in the Sahara and North Africa. For example, the ctenodactylids persist as relicts from a much older but now extinct radiation in Asia (Flynn *et al.* 1986, Wang 1994, Dashzeveg & Meng 1998), and the few African dipodids

Table 8. Earliest geologic occurrence of extant families and subfamilies of African Rodentia.

(3 spp.) represent outliers of the core diversity of Dipodidae, both as fossils and extant species, in Asia (Klingener 1984, Wang & Dawson 1994, Wang & Qiu 2000). Other taxa plausibly represent much younger (Pliocene–Pleistocene) incursions to North Africa, presumably following a circum-Mediterranean route (Cricetidae [Arvicolinae], Spalacidae [Spalacinae], Gliridae [*Eliomys*]).

The timing and direction of continental exchange are not so clear-cut for many groups whose distribution and diversity are centred in sub-Saharan Africa, although the conventional explanation emphasizes migration from Asia into Africa (Jacobs 1985, Winkler 1994, Flynn

& Jacobs 1999). For example, all African sciurids belong to an extensive radiation (Xerinae: Xerini and Protoxerini) that is notably abundant in sub-Saharan biomes (Mercer & Roth 2003, Steppan *et al.* 2004); Holarctic ground squirrels and chipmunks constitute a derived clade (Marmotini) within this subfamily. The other extant genus of African Gliridae, *Graphiurus*, is modestly speciose within sub-Saharan forests and woodlands and is the sole member of a distinctive subfamily (Graphiurinae) that represents the earliest phyletic branch within the family (Wahlert *et al.* 1993, Montgelard *et al.* 2003), which also occurs in Europe and Asia (Hartenberger 1994). A related graphiurine (*Otaviglis*) has been recently described from the late Miocene of Namibia, and *Graphiurus* itself is recorded from the latest Miocene of South Africa (Table 8); according to molecular estimates, differentiation of the graphiurine lineage dates to 40–50 mya (Montgelard *et al.* 2003). Living members of Nesomyidae are similarly known only from the sub-Saharan region (some fossil Dendromurinae documented from North Africa and Arabian Peninsula – see subfamily profile), and the several subfamilies compose a clade separate from, perhaps basal to, the radiation of Cricetidae and Muridae (Michaux *et al.* 2001, Jansa & Weksler 2004). The Miocene diversity of the family, including earliest records of extant genera, has been revealed by significant studies published since the middle 1990s (Table 8). Three of the five subfamilies of Muridae (Deomyinae, Leimacomomyinae, Otomyinae) are concentrated within the sub-Saharan region (*Acomys*, a deomyine, also occurs in North Africa and the Middle East). The murid subfamily Gerbillinae has a broader distribution throughout Africa and into the Middle East and central Asia, but early-branching clades of Gerbillinae (Ammodillini, Taterillini) predominantly lie within the sub-Saharan region (Pavlinov *et al.* 1990). The Murinae, too, has an extensive distribution within Africa, across Eurasia and into Indomalaya and Australia; generic and specific endemism within sub-Saharan biomes is pronounced and includes a few large, well-defined clades (Watts & Baverstock 1995a, Ducroz *et al.* 2001, Lecompte *et al.* 2002b). A molecular-clock estimate places the divergence between Deomyinae, Gerbillinae and Murinae in the early Miocene (Michaux *et al.* 2001). Bathyergidae (African mole-rats) is another family endemic to the sub-Saharan region and contains five strongly differentiated genera (Honeycutt *et al.* 1991). Molecular studies divulge startlingly older dates for phyletic divergence among bathyergids (middle Eocene, ca. 40 mya – Huchon & Douzery 2001) than presently reflected in palaeontological data (Table 8) and point to an autochthonous East African origin of the family (Faulkes *et al.* 2004).

Although Asia, or to a lesser extent Europe, seems the probable source-area for Africa's ancient (Eocene) rodent stocks, the foregoing examples implicate the continent as an important secondary centre for the origin (Oligocene–early Miocene) of major groups. The substantial taxonomic differentiation at the generic, subfamily and family levels, Miocene appearances of extant genera, and deep cladistic patterns all indicate a longer phase of phylogenetic differentiation of Rodentia within sub-Saharan Africa than can be presently documented by the fossil record. The rarity (early Miocene) or absence (Oligocene) of critical-aged, productive fossil sites within the region offers, at best, a precarious foundation to argue continental origins and intercontinental exchanges for many African rodent families. Palaeontological investigation continues, of course, and it is instructive that some of the more exciting discoveries of

earlier appearances have emerged from contributions of the past decade. Future phylogeographic studies that include ample species sampling of genera, subfamilies and families with both African and Asian geographic ranges (e.g. Hystricidae, Spalacidae, Muridae [Gerbillinae, Murinae]) would measurably improve our understanding of continental origin and directions of faunal interchange.

Biology

The immense variation in the biological characteristics of African rodents reflects the large number of species, their evolutionary diversity, and the very varied environments where they are found. This section provides a necessarily brief overview of the diversity of some aspects of the biology of the order. More detailed information may be found in each genus and species profile. General reviews are given in Delany & Happold (1979), Delany (1972, 1986) and Happold (2001); and the role of rodents in African ecosystems is discussed by Dieterlen (1989) and Happold (1996) for rainforests, Happold (1984) for deserts, and Happold (1983) for savannas. The amount of biological information on African rodents varies greatly depending on the species; for some, nothing is known because of their rarity and limited geographical distribution; for many, a limited number of observations are available; and for only a few species (those which are widespread, unusual, or of economic importance) there is substantial information. In spite of the impressive diversity of the order, few species are biologically well understood, and even the best-known species are not so well known as many of Africa's iconic large mammals that belong to far less speciose orders (Proboscidea, Primates, Carnivora, Perissodactyla and Ruminantia).

African rodents vary greatly in size; the majority weigh 20–80 g, but the smallest weighs only 3 g (*Mus haussa*), and the largest weigh ca. 3.25 kg (*Pedetes* spp.) and ca. 20 kg (*Hystrix* spp.). Most African rodents are typically 'mouse-like' or 'rat-like' but there are many that are very different; for example, jerboas (*Allactaga*, *Jaculus*) and springhares (*Pedetes*) have extremely long hindlimbs and jump like kangaroos; anomalures (*Anomalurus*, *Idiurus*) have large wing-like membranes so they can glide from tree to tree; and mole-rats (*Bathyergus*, *Georchychus*, *Heliophobius*) have blunt muzzles, cylindrical bodies, large short spatulate forelimbs, rudimentary (or non-existent) eyes, and huge incisor teeth (for excavating burrows). Because of the large number of species representing families of distant evolutionary origins, there are some interesting examples of ecological and morphological convergence: species of Dipodidae and Pedetidae are bipedal and saltatorial; species of Bathyergidae and Spalacidae are permanently subterranean; species of Muridae, Gliridae and Sciuridae all include some species that are arboreal; and species of Dipodidae and Gerbillinae have the ability to produce very concentrated urine and hence can live in very dry habitats devoid of free water. Likewise, convergence in form and biology occurs in distantly related taxa that inhabit similar but well separated habitats; for example the following genera occur, respectively, in the Sahara Arid BZ and the South-West Arid BZ: *Gerbillus* spp. and *Gerbillurus* spp., *Atlantoxerus* and *Xerus* spp., *Ctenodactylus* spp. and *Petromus typica*, and *Acomys* spp. and *Petromyscus* spp. The rich morphological variety exhibited by African rodents presupposes the remarkable diversity recorded in their life histories, habits and ecological niches.

Rodents are found throughout the African continent, in every biotic zone, and in almost every habitat from the driest of deserts to the wettest of rainforests. Most species are terrestrial, living on the surface of the ground; many of them rest in burrows or under rocks when inactive. Other species may be described as scansorial because they also clamber about in low vegetation close to the ground. Arboreal species (several genera of squirrels, *Graphiurus*, *Grammomys*, *Thallomys*) spend all (or most) of their time in large shrubs and trees, and rarely descend to the ground. Some small species are adapted for climbing on tall grasses (*Dendromys*, *Dendroprionomys*, *Prionomys*) and have opposable fingers and prehensile tails for holding on to slender grass stems. A number of genera (*Bathyergus*, *Georchychus*, *Heliophobius*, *Heterocephalus*) are subterranean and live permanently underground. Only a few species typically live in wet swampy habitats and are capable of swimming; such forms (*Deomys ferrugineus*, *Colomys goslingi* and *Malacomys* spp.) are characterized by relatively long limbs and large hindfeet. Most species are very habitat-specific, being found in only one or two habitats. In contrast, a few species (e.g. *Mastomys natalensis*, *Cricetomys gambianus*, *Thryonomys swinderianus*, *Hystrix* spp.) are widespread and habitat generalists.

The geographical range of many species is relatively well known from museum specimens and trapping records (see maps in each species profile). However, such geographical ranges do not provide any indication of the abundance of a species within its range. Abundance may be expressed either as the numbers of individuals captured using a standardized trapping method, or as a proportion (usually expressed as a percentage) that a species contributes to the community in which it lives, or as the density of individuals/unit area (such as the number of individuals of a species per hectare, or the total number of individuals of all species per hectare). Such measures may vary greatly between habitats and locations, and according to the time of year. Typical examples of proportional representation are: individuals of *Dasyms rufulus* comprise 14.6% of the community of trappable small mammals at Mount Nimba (Guinea), 9.2% in the savannas at Bolo (Côte d'Ivoire) and 7.5% in the savannas at Lamto (Côte d'Ivoire). *Dephomys defua* contributes 10% in four different rainforests in Ghana, *Heimyscus fumosus* contributes 4.6–20.5% (mean 11.5%) and forms the second or third commonest species of nine syntopic species in Gabon, and *Praomys daltoni* comprises 0–78% (mean 50%) at 11 localities in Nigeria. Density is a particularly useful measure of abundance because it provides actual numbers; for example, the density of *Hybomys univittatus* in forests of the Central African Republic was 3.02/ha (in lightly logged forest) and 4.14/ha (in heavily logged forest) (Malcolm & Ray 2000); the density of *Lophuromys flavopunctatus* in DR Congo varied from 9.8/ha (in savannas) to 19.6/ha (in dry seasonal swamps) (Misonne 1963); and the density of *Aethomys namaquensis* in different countries ranged from 2/ha in succulent Karoo, South Africa, to 5.4/ha in Namibia, 4–13/ha in Mozambique and 5.2–27.3/ha in Zimbabwe. Density also varies seasonally; e.g. the density of *Arvicanthis abyssinicus* in Ethiopia was 65–75/ha during the wet season and 130–250/ha during the dry season (Müller 1977), and in *Praomys tullbergi* in Nigerian rainforest, density ranged between 9.5/ha and 27.9/ha according to season over a period of three years (Happold 1977). Seasonal fluctuations in numbers tend to be smallest in species that live in rainforest, and largest in species that live in conditions where rainfall is low and unpredictable. Inter-annual fluctuations are typically rather large in dry localities; e.g. densities of *Taterillus*

pygargus in the sahel savanna of Senegal varied from 0/ha after the drought of 1972 to 180/ha after the good wet season of 1975 (Poulet 1978). For just a few species, live-trapping of individual animals over a long period of time has provided detailed information on population dynamics, home-ranges, movements and longevity (e.g. *Praomys tullbergi*, *Acomys spinosissimus*, *Mastomys natalensis*). Such relatively well-known species are the exception among African rodents. Many more have been rarely encountered and have very restricted geographical ranges, and hence very little is known about the biology of such species. Whether this 'rarity' is real or due to inappropriate methods of study is uncertain; whatever the reason, obtaining information on such species provides a challenge for ecologists in the future. The examples given above refer only to single species; other measures concern all the species that comprise a community; these include 'species richness' (= the number of species in the community) and density (= the total number of individuals of all species known to be alive [KTBA]) in the community. These community measures are especially useful when assessing trophic interactions between species, the overall impact of the community on its environment, and the interactions between different species in the community, especially in respect of reproductive strategy and seasonal changes in demography. For example, the species richness in a rainforest in SW Gabon was 11 species of rodents (plus ten species of shrews) (Nicolas & Colyn 2003; Nicolas *et al.* 2005). In a similar rainforest in Nigeria, species richness was seven species of rodents (and two species of shrews) and density, which varied according to season, was 14.3–25/ha (Happold 1977). (Equivalent data on numbers are unavailable for Gabon.) Similar variations are recorded in savanna habitats: in *Brachystegia* savanna in Malawi, species richness was seven species of rodents (and one species of sengi [Macroselidae]) and density was 3–21/ha according to season (Happold & Happold 1991); equivalent data for thornbush savanna in Malawi was seven species of rodents (and one species of shrew) and 1–33/ha (Happold & Happold 1990). In *Brachystegia* savanna in Zimbabwe, species richness was seven species of rodents (and one species of shrew) and density was 2–10/ha (Linzey & Kesner 1997a). Habitat has a very strong influence on community structure; for example, species richness and density of small rodents during one year in Zimbabwe varied greatly in five neighbouring habitats as follows: riverine grasslands – 7 spp. 1–36/ha; miombo woodland – 7 spp., 2–10/ha; mopane woodland – 5 spp., 1.6–19/ha; talus – 4 spp., 8–25/ha; and thicket – 0.8–2/ha (Linzey & Kesner 1997a) (see also below). The reasons for such variation between habitats are uncertain and need further investigation; but the fact that such variations do occur implies differing levels of resources, differing levels of exploitation by rodents of these resources, and differing numbers and diversity of rodent predators in each habitat.

Rodents show a wide range of reproductive methods and reproductive strategies. The strategy of any particular species is determined partly by its phylogeny, but also by the environment and location. Species vary greatly in their fecundity: squirrels, anomalurids and *Pedetes* have only 1–2 young per litter; many species have 3–6 young per litter; some have up to 10/litter; and the most fecund species (e.g. *Mastomys natalensis*, *Heterocephalus glaber*) may have as many as ca. 20/litter. Litter-size within a species may vary geographically, seasonally and in relation to the size/weight of the female; for example in *Saccostomus campestris* mean embryo number varies from 4.8 (South Africa) to 7 (Botswana) (see profile for

references); in *Gerbilliscus nigricaudus* mean litter size is 4.2 in the dry season and 5.5 in the wet season (Neal 1982); and in *Acomys spinosissimus* mean litter-size is 2.9 for smaller females and 3.6 for larger females (Hanney 1965). Pregnancy and lactation is adaptively timed to ensure a high survival rate for the young. Because small rodents have relatively short gestations (ca. 25–40 days), they can be very responsive to changes in climate. Hence the start of the wet season (in tropical climates), or the end of 'winter' (in temperate Africa) initiates the reproductive process, and the young are born and weaned while the favourable conditions last. Within this reproductive period, many species show a 'peak' of reproductive activity (as measured by the percentage of adult females that are pregnant). In *Beamys hindoi*, for example, pregnancy rate ranged from 20% to 60% during the nine months of reproductive activity (Fitzgibbon *et al.* 1995), and in *Hylomyscus denniae* in E DR Congo, pregnancy rate ranged from 80% (dry season/early wet season) to 9% (wet season) and then to 47% (late wet season/early dry season) (F. Dieterlen unpubl.). Larger rodents, with longer gestations (e.g. 100–120 days in *Atherurus africanus*, 112 days in *Hystrix cristata*, ca. 80 days in *Pedetes capensis*) are unable to respond so quickly to changing environmental conditions. Because of the short gestation of many species of small rodents, a female may have several litters during the time when conditions are favourable for reproduction. A strategy that includes short gestation, rapid growth of young to independence and a postpartum oestrus (so the female is able to conceive again immediately after parturition) is especially important to species where favourable conditions are short-lived and/or unpredictable. A corollary of small size is a short life-span (often only a few months) and hence it is necessary for small rodents to attain sexual maturity rapidly, to have large litters, and to produce several litters in quick succession in order to maximize their lifetime reproductive success. For *Acomys wilsoni* in Kenya (mean embryo number: 2.2), estimates suggest 7.9 litters/female/year and an annual production of 17.4 young/female/year (Neal 1983).

Population structure within a species is a consequence of the characteristics of its reproduction and environment quality. Again, there are few long-term studies that document the changing structure of rodent populations. In *Praomys tullbergi*, a rainforest species that reproduces in most months of the year (with two peaks of reproductive activity) and has comparatively small litters, the population structure remains more or less constant throughout the year; young, subadults and adults are represented in all months (with the ratio of each changing slightly month by month) (Happold 1977). In contrast, the savanna-dwelling *Mastomys natalensis* reproduces only during the wet season and early dry season and has comparatively large litters; the population consists mostly of subadults at the end of the dry season, mostly adults and many young during the wet season and early dry season, and mostly subadults again (after most of the reproductive adults have died) in the mid- and late dry season. These examples (which probably represent the two extremes of population structure) also illustrate another aspect of demography in small rodents: species that occupy relatively constant and predictable environments throughout the year experience only small population fluctuations (e.g. the maximum number of *Praomys tullbergi* in Nigerian rainforest is only 2–3 times the minimum number; Happold 1977); whereas those in environments that are less predictable and have large seasonal variations in climate and resources exhibit larger fluctuations (e.g. the maximum number of *Mastomys natalensis* in

thornbush savanna is up to 33 times the minimum population size; Happold & Happold 1991).

Because most species of rodents are small, only a limited volume of food can be ingested, and hence that food needs to be highly nutritious. The majority of species of African rodents feed on plants, and may be broadly categorized as herbivores (those feeding on grasses, leaves and/or herbs), granivores (seeds, nuts) or frugivores (fruit and flowers). Others are omnivores, feeding on plants and animals (usually arthropods), and a very few are wholly insectivores. For those species that have been investigated, the diet tends to be rather precise; preferred food items (i.e. those that are most nutritious in relation to their bulk) are selected, and most species alter their diet seasonally. For example, squirrels are primarily granivorous and frugivorous, although some species (e.g. *Funisciurus lemniscatus*, *F. pyrropus*, *Myosciurus pumilio*) are omnivorous because they also eat significant amounts of insects (mainly termites). Most glirids are omnivorous. Most species of Muridae are herbivorous or omnivorous, feeding on a variety of grasses, herbs, seeds and fruits; many are opportunistic and although basically herbivorous, will include a small amount of arthropod food in their diet when other foods are unavailable during some seasons of the year. A few species are wholly herbivorous (*Arvicanthis* spp., *Otomys* spp., *Ctenodactylus* spp.). Others are consistently omnivorous, with a high percentage of arthropods and worms in their diet (e.g. *Acomys* spp., *Lophuromys* spp., *Uranomys ruddi*, *Heimyscus fumatus*, *Hybomys* spp., *Malacomys* spp.). Only a few species are known to be wholly insectivorous (*Deomys ferrugineus*, *Colomys goslingi*). Subterranean species (species of Bathyergidae and Spalacidae) feed on a variety of underground corms, bulbs, tubers, fibrous roots and rhizomes. Perhaps because of their tropical and sub-tropical distributions, it is unusual for African rodents to store food, although there are some exceptions: some squirrels collect nuts, which are placed in caches; *Beamys hindoi*, *Cricetomys* spp. and *Saccostomus* spp. carry seeds in their cheek pouches and store them in their burrows for later consumption; and some subterranean species store geophytes. The foregoing generalizations on food habits underscore the necessity of thorough, year-round, trophic studies of African rodents, especially for species in the families Nesomyidae and Muridae.

The behaviour of African rodents has not been studied as extensively as that for the larger mammals. Their small size, nocturnal activity and lack of visibility make it very difficult to pursue behavioural studies on rodents (and other small mammals). However, there are several notable studies on diurnal species that are easily visible during the daytime (see, for examples, profiles on several species of Sciuridae, *Rhabdomys pumilio*, *Thallomys* spp., *Pedetes capensis*, *Ctenodactylus gundi*, *Thryonomys* spp. and *Hystrix* spp.). Additional studies (which provide information on sociality, agonistic behaviour, nesting behaviour and maternal behaviour) have been made on several species in captivity. Although most species tend to be asocial and/or solitary except for times during reproductive activity, some species form loose aggregations and social groups (e.g. squirrels, gundis, porcupines). All species of rodents that have been studied show many forms of intra- and inter-specific communication; these include vocal (e.g. calls, squeaks, whistles), visual (e.g. amicable or aggressive displays, postures, tail-flicking, etc.), non-vocal auditory (foot-drumming, tooth-chattering) and olfactory (scent-marking) signals. Territoriality is well-developed in some species and territories are maintained by visual and olfactory signals, and also (in some species) by fighting and chasing. Maternal behaviour has been well-studied (usually in

captivity) in some species; most mothers are solitary when raising their young but there are interesting exceptions such as some species of *Acomys* (Muridae: Deomyinae) in which there is social care of the young by the several mothers. One of the most studied species, *Heterocephalus glaber* (Bathyergidae), has a social system resembling that of eusocial insects. Within any family, there may be some species that are asocial and territorial, and others that are highly social (see, e.g. Bathyergidae, Sciuridae, Muridae: Otomyinae).

Rodents play an important role in ecological processes in Africa due to the many species present, their collectively widespread distributions and the sometimes large population numbers within particular habitats. Because the vast majority of species are herbivores and granivores, they assume a major role in recycling nutrients. Granivorous species transport seeds away from the parent plant and bury them, thus increasing seed dispersal. By their normal activities, rodents change the environment in which they live – a process known as ‘ecological engineering’; familiar examples include burrowing whereby the soil profile is altered and new soil is brought to the surface where it can act as ‘seed-beds’ for plants; defecating at regular latrines, which provides small areas of increased nutrients which promotes plant growth; and feeding on grasses and herbs, which promotes plant growth (in the same way as do larger herbivorous mammals). Although the influence of one individual rodent may seem trivial (compared with that of a mega-herbivore), the very large numbers of rodents in many ecosystems mean that their total influence is not inconsiderable. The only quantitative data available showed that in the tall grass plains of the Serengeti (where there are many large herbivores), small mammals utilized 69 kg/ha (= 1.2% of the total) of the annual grass biomass compared with 1122 kg/ha (=18.8% of the total) for the large mammals (Sinclair

1975). At times, rodents may be detrimental to human endeavours; some species (e.g. *Mastomys* spp., *Gerbillus* spp.) destroy seeds and crops in agricultural fields, and also feed on stored grains in houses and granaries. The role of rodents in African savanna and rainforest ecosystems has been reviewed by Happold (1983, 1996).

Rodents are important prey for many small and medium-sized carnivores such as mongooses, genet, civets, small canids, small felids, owls (especially *Tyto alba* and *T. capensis*), hawks and snakes (see entries under ‘Predators, Parasites and Diseases’ in each species profile). For example, Giant Root-rats *Tachyoryctes macrocephalus* form 47% and *Lophuromys melanonyx* form 40% of the food of Ethiopian Wolves *Canis simensis* (Sillero-Zubiri & Gottelli 1995); at least 14 species of rodents form nearly 30% of the prey of seven species of small carnivores in the rainforests of the Central African Republic (the other significant prey was shrews, arthropods and herpetofauna) (Ray 1998); and small rodents formed almost all of the food of African Grass-owls *Tyto capensis* on Zomba Plateau, Malawi, where four species (*Otomys angoniensis*, *Dasymys incomtus*, *Pelomys fallax* and *Dendromus nyikae*) comprised the majority of the prey (Happold & Happold 1986). Humans are also important predators of some species such as *Cricetomys emini*, *C. gambianus* and *Thryonomys* spp. Some species of rodents are responsible directly (or indirectly through parasites that they carry) for the transmission of diseases of humans; well-known examples are some species of *Gerbillus* (formerly *Tatera*) and *Gerbillus* (plague), *Meriones* spp. and *Psammomys obesus* (leishmaniasis), *Rattus rattus* and *R. norvegicus* (plague) and *Mastomys erythroleucus* and *M. natalensis* (Lassa fever and other diseases). Control measures may be necessary when population numbers of these species become too large close to human environments.

Table 9. African families of the order Rodentia.

| Family | Length of tail ^a | Tail ^b | Pelage texture | Cheekteeth | Jaw musculature ^c | HB (typical size or range) (mm) ^d | Ecology and form |
|-----------------|-----------------------------|-------------------|--------------------|--|------------------------------|--|--|
| Anomaluridae | L | H | Soft | ⁴ / ₄ | Hy | 63–75, 280–380 | Arboreal; patagia present (except in <i>Zenkerella</i>) |
| Gliridae | L | H | Soft | ⁴ / ₄ | Hy, My | mostly 60–100 | Arboreal; patagia absent |
| Petromuridae | L | H | Soft | ⁴ / ₄ | Hy | 140–220 | Terrestrial, rupicolous |
| Sciuridae | L | H | Soft | ⁴ / ₄ , ⁵ / ₄ | Sc | 110–126, 180–240 | Arboreal; patagia absent; one species 60–70 mm |
| Dipodidae | L | T | Soft | ³ / ₃ | Hy | 98–118, 137–160 | Terrestrial; elongated hindlimbs |
| Pedetidae | L | T | Soft | ³ / ₃ | Hy | 350–430 | Terrestrial, elongated hindlimbs |
| Nesomyidae | L | P | Soft | ³ / ₃ | My | 50–63, 270–300 | Terrestrial, some scansorial |
| Cricetidae | L | P | Soft | ³ / ₃ | My | 100–124, 180–300 | Terrestrial |
| Muridae | L (some S) | P | Soft (some coarse) | ³ / ₃ | My | 44–52, 135–190 | Terrestrial, some scansorial, some rupicolous |
| Ctenodactylidae | S | H | Soft | ³ / ₃ (⁴ / ₄) | Hy | 125–230 | Terrestrial, rupicolous |
| Bathyergidae | S | P | Soft | ⁴ / ₄ (up to ⁶ / ₆) | Hy | 90–190 | Subterranean |
| Hystriidae | S | P | Spines | ⁴ / ₄ | Hy | 650–850 | Terrestrial |
| Thryonomidae | S | P | Coarse | ⁴ / ₄ | Hy | 400–790 | Terrestrial |
| Myocastoridae | S | P | Coarse | ⁴ / ₄ | Hy | 470–570 | Aquatic; terrestrial |
| Spalacidae | S or A | P or NA | Soft | ³ / ₃ | My | 160–200, 225–315 | Subterranean |

^a S = tail short <50% of HB; L = tail longer >50% of HB; A = tail absent (or not visible externally).

^b P = naked or with small bristles; H = covered with long hairs; T = well-developed tuft of hair at tip; NA = not applicable.

^c Hy = hystricomorphous; My = myomorphous; Sc = sciuriomorphous.

^d Approximate and typical sizes. Where there is wide variation within a family, the smallest and largest species are indicated.

Systematic arrangement of Rodentia in *Mammals of Africa*

The 15 families of African rodents (14 indigenous and the introduced Myocastoridae) are treated in accordance with the phylogenetic relationships reviewed above and as presented by Carleton & Musser (2005) in the Third Edition of *Mammal Species of the World* (Wilson & Reeder 2005). The families, in the sequence given in this volume (Table 6, see also Table 9), are Sciuridae, Gliridae, Dipodidae, Spalacidae, Nesomyidae, Cricetidae, Muridae, Anomaluridae, Pedetidae, Ctenodactylidae, Bathyergidae, Hystricidae, Petromuridae, Thryonomyidae and Myocastoridae. Four families (Spalacidae, Nesomyidae, Cricetidae, Muridae) are further divided into subfamilies, which are arranged alphabetically, as are the genera within each subfamily and the species within each genus.

Figure 6. The bones and terminology of the skull of a 'typical' murine rodent (*Praomys tullbergi*). 1 Angular process, 2 Anterior palatal foramen, 3 Auditory bulla, 4 Auditory meatus, 5 Basisphenoid, 6 Basisphenoid, 7 Braincase, 8 Cheekteeth (molar row), 9 Condylar process, 10 Coronoid process, 11 Diastema, 12 Foramen magnum, 13 Frontal, 14 Glenoid fossa, 15 Incisor, 16 Infraorbital foramen, 17 Interorbital constriction, 18 Interparietal, 19 Jugal, 20 Lachrymal, 21 Masseteric knob, 22 Mastoid, 23 Mastoid process, 24 Maxilla, 25 Maxillary process (zygomatic arch), 26 Mesopterygoid fossa, 27 Nasal, 28 Occipital condyle, 29 Occipital, 30 Orbit, 31 Palate, 32 Palatine, 33 Paraoccipital process, 34 Parietal, 35 Posterior palatal foramen, 36 Premaxilla, 37 Pterygoid process, 38 Rostrum, 39 Squamosal process (zygomatic arch), 40 Squamosal, 41 Supraoccipital crest (if present), 42 Supraorbital ridge (if present), 43 Zygomatic arch (Zygoma), 44 Zygomatic plate.

Size categories

In the Descriptions, an indication of the size of each species is recorded comparatively to other species in the family. The size categories, based on mean head and body length (HB), are:

| Family | Size categories (mean head and body length) |
|---|---|
| Dipodidae, Spalacidae, Nesomyidae, Cricetidae, Muridae, Pedetidae, Ctenodactylidae, Hystricidae, Petromuridae, Thryonomyidae, Myocastoridae | Very small: 50–84 mm
Small: 85–119 mm
Medium-sized: 120–154 mm
Large: 155–189 mm
Very large: 190–350 mm
Extremely large: >350 mm |
| Gliridae | Small: 70–99 mm
Medium: 100–129 mm
Large: 130–159 mm |
| Sciuridae, Anomaluridae | Very small: 70–119 mm
Small: 120–169 mm
Medium sized: 170–219 mm
Large: 220–269 mm
Very large: 270–421 mm |
| Bathyergidae | Small: <100 mm
Medium-sized: 101–200 mm
Large: >200 mm |

The length of the tail, expressed as a percentage of the length of HB, is described as very short (<30%), short (30–77%), long (78–110%), very long (111–160%) or extremely long (>161%). The names of the bones of the skull are shown in Figure 6, and the nomenclature of the cusps on the cheekteeth of a murine rodent are shown in Figure 7.

Michael D. Carleton & D. C. D. Happold

Figure 7. A schematic view of the upper left cheek teeth (M^1 , M^2 , M^3) of a murine rodent showing the nomenclature of the cusps. Cusps labelled as 1, 2, etc. (= t_1 , t_2 , etc.). Inner (lingual) side on left, outer (labial) side on right. Cusps = black dots. Lines = lophs or ridges joining cusps. t_2 on M^2 and M^3 never or rarely present. t_3 of M^3 very small or absent. t_5 and t_6 of M^3 usually joined. Wear on occlusal surface (with age and use) obliterates the cusp pattern.

The Sciuridae is a polygeneric family of rodents distributed throughout most of the Americas, Eurasia and Africa, in habitats ranging from alpine to tropical and from desert to rainforest. There are 51 genera and 277 species in the family (Thorington & Hoffmann 2005). The Sciuridae is divided into five subfamilies, with all African squirrels included within the subfamily Xerinae, which also includes all the North American and northern Eurasian ground squirrels. The squirrels are a very successful group, widespread on all continents except Australia and Antarctica. The present fauna of South America includes three genera and 19 species, North America has eight genera and 83 species, Europe has four genera and six species, and Asia has 22 genera and 92 species. Africa has ten genera and 37 species of squirrels, including the introduced Grey Squirrel *Sciurus carolinensis* (subfamily Sciurinae), in South Africa. The anomalures (or scaly-tailed flying squirrels) of Africa belong to a different family of rodents, the Anomaluridae.

Squirrels are small to large rodents, usually with a long well-haired tail and a relatively short rostrum. Some species are rather plain with a uniform reddish or brownish colouration, others are very colourful. Most squirrels have long tails, with long lateral hairs and shorter dorsal and ventral hairs; the tail may be slender or bushy and in some species has noticeable rings or bands of colour along its length. Longitudinal lateral side-stripes are common among terrestrial squirrels and some genera of arboreal squirrels. There are four digits on the forefoot (Digit 1 small or vestigial) and five long digits on the hindfoot. The skull is sciuro-morphous, with the anterior deep masseter muscle originating on the zygomatic plate and (except in *Paraxerus* and *Funisciurus*; Thorington & Darrow 1996) the lateral surface of the rostrum. No part of the masseter muscle passes through the infraorbital foramen. Postorbital process present. Supraorbital ridge with small foramen (or notch) at anterior end in some genera. The masseteric tubercle, a bony knob-like projection on the maxilla bone anterior to the cheekteeth, is present in some genera and a useful diagnostic character. Dental formula is $I \frac{1}{1}, C \frac{0}{0}, P \frac{1}{1} \text{ or } \frac{2}{1}, M \frac{3}{3} = 20 \text{ or } 22$. There are four upper cheekteeth (one premolar (= P^4) and three molars) in *Epixerus*, most *Heliosciurus*, *Myosciurus* and *Protoxerus*, and five upper cheekteeth (two premolars (P^3 , which is often very small, and P^4) and three molars in *Allosciurus*, *Atlantoxerus*, *Funisciurus*, *Paraxerus* and *Xerus*. Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

Squirrels are terrestrial and arboreal, and one group of arboreal squirrels (the non-African Pteromyini) consists of species that are also able to glide. Most terrestrial species live in underground burrows, and

most arboreal squirrels make nests in tree hollows or on tree branches. Many squirrels feed extensively on hard seeds, but diets vary greatly from soft fruit or leaves to fungi, insects or other animal matter. Many non-African species of squirrels (e.g. Marmots, Chipmunks) hibernate, some for seven months each year. A few species aestivate during the hottest months of the year. Dwarfism has evolved independently three or four times in different groups of arboreal squirrels, in Africa, Asia and South America (Mercer & Roth 2003, Thorington *et al.* 1997). On all three continents, these diminutive squirrels have evolved a form of foraging known as bark-gleaning. The African Pygmy Squirrel *Myosciurus* is one of the smallest species, averaging 16 g in weight. The largest terrestrial squirrels are the Marmots *Marmota*, some of which may reach 9 kg. In contrast, the largest African ground squirrels, *Xerus*, do not exceed 1 kg. The largest tree squirrels are the Oriental Giant Squirrels *Ratufa*, with some individuals exceeding 2 kg. The largest African tree squirrels, *Protoxerus*, average 700 g. Most squirrels are solitary, with each individual having its own home-range. Some species are territorial. Colonial community structure and complex social behaviour occur in a number of terrestrial squirrels, especially the Prairie Dogs *Cynomys*, Marmots *Marmota* and Ground Squirrels *Spermophilus* of North America. Some African Ground Squirrels are also colonial (*Atlantoxerus*, *Xerus inauris* and *Xerus princeps*) but most African arboreal squirrels are not, and are seen singly, in pairs, or in small groups.

Squirrels exhibit a variety of reproductive strategies, with average litter-sizes ranging from slightly more than one to more than nine. The largest litter-sizes are found among the North American ground squirrels, which have only a single litter per year; e.g. in *Spermophilus*, the average litter-size ranges from 3.3 to 9.3, and in *Marmota* from 3.4 to 4.2 (Heaney 1984). The largest of these may defer breeding until two or three years of age and produce litters every other year. North American tree squirrels have smaller litter-sizes (averaging 1.9–4.5 young), and commonly have more than one litter per year. In contrast, African Ground Squirrels have 2–4 young/litter (Moore 1961), and African tree squirrels have only 1–2 young/litter (Emmons 1979a). African tree squirrels are born at a more advanced stage of development and are ready to leave the nest at an earlier age than North American tree squirrels: e.g. the *Paraxerus* leave at 3–4 weeks of age, and young of *Tamiasciurus* and *Sciurus* at 5–9 weeks (Ferron 1984). Emmons (1979a) attributes this to a greater risk of nest predation in the African tropics.

The earliest fossil squirrel is *Douglassia* of the late Eocene of North America (Emry & Thorington 1982). Squirrels (*Palaeosciurus*) appear in the European fauna in the early Oligocene (Vianey-Liaud 1974), immediately after the time known as the ‘grande coupure’, when many Asian species entered the European fauna. The African Ground Squirrels are first known from *Heteroxerus* in the late Oligocene of Europe. The genus *Getuloxerus*, perhaps synonymous with *Atlantoxerus* (the extant Barbary Ground Squirrel), is found in Spain and North Africa in the late Miocene (Black 1972a). Squirrels are first found in sub-Saharan Africa in the Miocene (Lavocat 1973). *Volcanisciurus* of the early Miocene is not referable to any modern tribe. *Kubwaxerus* of the upper Miocene is closely related to the extant genera *Epixerus* and *Protoxerus* and is the earliest known member of the Protoxerini

Table 10. Genera in the family Sciuridae.

| Genera | Posterior end of bony palate | Masseteric tubercle | Side-stripe on each flank | Mean HB* (mm) | Number of cheekteeth (upper/lower jaw) | Mean GLS* (mm) | Notes |
|------------------------------|--|---------------------|------------------------------------|---------------|--|----------------|---|
| <i>Allosciurus</i> (1 sp.) | In line with posterior end of M ³ | Small | None | 240 | ⁵ / ₄ | 59 | Terrestrial/arboreal. West African rainforests (Liberia/Sierra Leone to Ghana) |
| <i>Atlantoxerus</i> (1 sp.) | Considerably posterior to M ³ | Prominent | 1 (+ single mid-dorsal stripe) | 194 | ⁵ / ₄ | 46 | Terrestrial. NW Africa |
| <i>Epixerus</i> (1 sp.) | Posterior to M ³ | Not prominent | None | 284 | ⁴ / ₄ | 69 | Terrestrial and arboreal. Rainforests of West and central Africa |
| <i>Funisciurus</i> (9 spp.) | Approximately in line with posterior end of M ³ | Not prominent | 1 (sometimes obscure) ^a | 152–211 | ⁵ / ₄ | 38.8–52.7 | Arboreal and tangles. Rainforests of West and central Africa; some spp. extend to relict forests in savanna |
| <i>Heliosciurus</i> (6 spp.) | Approximately in line with posterior end of M ³ | Prominent | None | 196–237 | ⁴ / ₄ ^b | 42.7–54.2 | Arboreal. Widespread. Rainforest and savanna of sub-Saharan Africa |
| <i>Myosciurus</i> (1 sp.) | Approximately in line with posterior end of M ³ | Absent | None | 66 | ⁴ / ₄ | 21.3 | Arboreal. Rainforests SE Nigeria to Gabon |
| <i>Paraxerus</i> (11 spp.) | Approximately in line with posterior end of M ³ | Prominent | None, 1 or 2 ^c | 102–230 | ⁵ / ₄ | 30.6–55.6 | Rainforest and tangles, woodland savanna. West, central and East Africa |
| <i>Protoxerus</i> (1 sp.) | Approximately in line with posterior end of M ³ | Not prominent | None | 297 | ⁵ / ₄ or ⁴ / ₄ | 67.8 | Arboreal. Rainforest of West and central Africa |
| <i>Xerus</i> (4 spp.) | Considerably posterior to M ³ | Prominent | 1 ^d | 212–259 | ⁵ / ₄ | 50.7–60.8 | Terrestrial. Savanna and semi-arid; sub-Saharan Africa |

* Where range of values given, smaller value refers to smallest species in genus and larger value to largest species in genus.

^a Except *F. isabella*, with two black stripes on each flank. ^b Except *H. ruwenzorii* – ⁵/₄ with small P³ present. ^c Plus single mid-dorsal stripe in two species with two stripes on each flank (*P. boehmi*, *P. alexandri*). ^d Except *X. rutilus*.

(Cifelli *et al.* 1986). It is also the largest known African squirrel and is estimated to have weighed 1.4 kg. It had the thickest incisors of any known squirrel and probably, like *Epixerus*, subsisted on very thick nuts. *Paraxerus* from the Pliocene of East Africa is the earliest known of the *Paraxerus*–*Funisciurus* group of squirrels.

Because of recent molecular studies (Mercer & Roth 2003, Steppan *et al.* 2004), the family Sciuridae is now divided into five subfamilies (Thorington & Hoffmann 2005); only one of these – the Xerinae – is represented in Africa. Within this subfamily there are three tribes: the Xerini, the Protoxerini and the Marmotini, the first two tribes containing all the African squirrels. The Xerini includes the two genera of African Ground Squirrels, *Xerus* and *Atlantoxerus*. The Protoxerini includes seven genera: the Sun Squirrels *Heliosciurus*, the African Giant Squirrel *Protoxerus*, the Slender-tailed Squirrel *Allosciurus*, the Splendid-tailed Squirrel *Epixerus*, the African Bush Squirrels *Paraxerus*, the Rope Squirrels *Funisciurus* and the African Pygmy Squirrel *Myosciurus*. These tribal assignments, and the presence of Xerini in the fossil record of Europe, suggest that the Xerini invaded Africa from Eurasia. The Protoxerini are endemic to Africa and may have evolved there from an unidentified ancestor. The nine genera of endemic African squirrels (Table 10) are listed here alphabetically by genus; additionally there is a tenth genus, *Sciurus*, which has been introduced into South Africa.

Allosciurus: Large unstriped arboreal squirrel of West Africa, with long slender non-bushy tail. Skull: rostrum curved down anteriorly,

supraorbital notch present, cheekteeth ⁵/₄.

Atlantoxerus: Ground Squirrel of North Africa. Three pale longitudinal stripes on back. Skull: bony palate extends well behind third molar, cheekteeth ⁵/₄, masseteric tubercles prominent. (1 sp.)

Epixerus: Large unstriped, terrestrial rainforest squirrel. Bushy tail with ventral V-shaped black and white pattern. Skull: bony palate ends in line with posterior end of third molar, cheekteeth ⁴/₄, masseteric tubercles not prominent, skull sutures still prominent in adult between parietal bones and surrounding interparietal bone. (1 sp.)

Funisciurus: Mostly small forest squirrels, often with a side-stripe on each side of body. Skull: bony palate ends in line with posterior end of third molar, cheekteeth ⁵/₄, cheekteeth flat-crowned, fossa for origin of anterior deep masseter muscle does not extend onto the rostrum. (10 spp.)

Heliosciurus: Medium to large arboreal forest squirrels of sub-Saharan Africa. Skull: bony palate ends in line with posterior end of third molar, cheekteeth ⁴/₄, third premolar absent in all but one species. Prominent masseteric tubercles, fossa for origin of anterior deep masseter muscle extends onto the rostrum. (6 spp.)

Myosciurus: Pygmy tree squirrel. Length of head and body less than 7.5 cm. Skull: bony palate ends in line with posterior end of third molar, cheekteeth ⁴/₄, skull length less than 25 mm, body mass less than 20 g. (1 sp.)

Paraxerus: Diverse group of forest and bush squirrels, some species with side-stripes, some without side-stripes. Skull: bony palate

ends in line with posterior end of third molar, cheekteeth $5/4$, fossa for origin of anterior deep masseter muscle does not extend onto the rostrum, mandibular cheekteeth cuspidate, upper cheekteeth flat-crowned. (11 spp.)

Protoxerus: One of the largest arboreal forest squirrels of sub-Saharan Africa. Tail not bushy. Skull: bony palate ends in line with posterior end of third molar, cheekteeth $4/4$, masseteric tubercles not prominent, fossa for origin of anterior deep masseter muscle extends onto the rostrum, skull sutures fused in adult between parietal bones and surrounding interparietal bone. (1 sp.)

Sciurus: Exotic species found only in parts of South Africa. No stripes on back. Skull: bony palate extends well behind third molar; cheekteeth $5/4$, masseteric tubercles not prominent, fossa for origin of anterior deep masseter muscle does not extend onto the rostrum. (1 sp.)

Xerus: Ground squirrels of sub-Saharan Africa. Bristly fur; most species have a white side-stripe on each side of body. Skull: bony palate extends well behind third molar, cheekteeth $5/4$, masseteric tubercles prominent. (4 spp.)

Richard W. Thorington, Jr

GENUS *Allosciurus* Slender-tailed Squirrel

Allosciurus Conisbee, 1953. *A list of Names proposed for Genera and Subgenera of Recent Mammals*: 6.

Monotypic genus. A large squirrel confined to the Rainforest BZ (Western Region). The characters of the genus include comparatively large size (mean HB 240 mm), back and flanks without longitudinal side-stripes, and long slender hairy tail (mean 298 mm), which is longer than HB (cf. *Protoxerus*). Females have four pairs of nipples; presence of baculum in ♂ not known. The skull is characterized by the curved-down rostrum (in lateral view), supraorbital notch (on supra-orbital ridge at lateral side of frontal bone) open above the orbit (not a foramen), infraorbital foramina large and oval, masseteric knob small, five upper cheekteeth and auditory bullae well developed, extending ventrally well below the line of the cheekteeth.

The single species, *Allosciurus aubinnii*, is frequently considered as belonging to *Protoxerus*, but its many unique features indicate that it should be placed in its own genus (see Thomas 1909a, Ellerman 1940, 1941, Rosevear 1969, Grubb *et al.* 1998; *contra* Moore 1959, Amtmann 1966, Thorington & Hoffmann 2005). *Allosciurus* differs from *Protoxerus* and *Epixerus* (and from *Heliosciurus* where indicated) in a number of important ways: (1) skull with unusual shape, relatively high, strongly convex in nasofrontal region with down-curved rostrum (cf. not down-curved in *Protoxerus*, *Epixerus* and *Heliosciurus*); (2) cheekteeth always $5/4$

(cf. $4/4$ in *Heliosciurus*, though $5/4$ in *Heliosciurus ruwenzorii* and rarely in some *Epixerus* specimens); (3) skull length <60 mm (cf. >65 mm); (4) supraorbital notch present (cf. closed to form supraorbital foramen – and in *Heliosciurus*) (Figure 8); (5) no sharp boundary between hair of flanks and underparts (cf. sharp boundary between hairs of flanks and relatively hairless underparts); (6) tail dark-coloured, with long black tips to hairs (cf. tail marked with dark and pale bands – and in *Heliosciurus*); (7) colouration dark (cf. relieved by light speckling and/or reddish tones – and in *Heliosciurus*).

Allosciurus forms a monophyletic clade with *Heliosciurus*, *Protoxerus* and *Epixerus* (Moore 1959).

Peter Grubb

Allosciurus aubinnii.

Figure 8. Skull and mandible of *Allosciurus aubinnii* (BMNH 45-331).

***Allosciurus aubinnii* SLENDER-TAILED SQUIRREL (AUBINN'S SQUIRREL)**

Fr. Écureuil d'Aubinn; Ger. Dünnschwanzhörnchen

Allosciurus aubinnii (Gray, 1873). Ann. Mag. Nat. Hist., ser. 4, 12: 65. Fanti, Ashanti Province, Ghana.

Taxonomy Originally described in the genus *Myrsilus*. Rosevear (1969) considers there to be sufficiently important differences in the skull and pelage for this species to be placed in its own genus, *Allosciurus*, separate from *Protoxerus*. Grubb *et al.* (1998) also place the species in *Allosciurus* (see genus profile). In contrast to *Protoxerus*, *Allosciurus* has no trace of red or rufous in the pelage, the tail lacks any white rings or banding, and the rostrum is down-curved. Hoffmann *et al.* (1993) and Thorington & Hoffman (2005) retain the species in the genus *Protoxerus*, but invoke *Allosciurus* as a subgenus. Synonyms: *salae*. Two subspecies. Chromosome number: not known.

Description Large dark slender squirrel without any other special colouring or marking. Dorsal pelage, head and limbs, dark brown to brownish-black, slightly speckled with yellow or buff; hairs brownish-black with 2–3 narrow, pale yellow bands. Ventral pelage similar but paler than dorsal pelage. When viewed from side, head has rounded profile due to down-curved rostrum. Ears short and rounded with dense hairs on outer surface. Tail long (ca. 125% of HB); slender and not bushy; black with intermixture of yellow or buff towards tip; hairs long (ca. 35 mm), mostly black at base, and with wide pale bands towards tip. Skull heavily built but less so than in *P. stangeri* and *Epixerus ebii*; rostrum down-curved, supraorbital ridge with open notch; cheekteeth $5/4$; posterior end of bony palate in line with posterior end of upper M^3 ; masseteric tubercle not prominent (see also genus profile). Nipples: 1 + 1 + 1 + 1 = 8.

Geographic Variation

P. a. aubinnii: Ghana, Côte d'Ivoire. Pelage as described above.

P. a. salae: Liberia (and probably Sierra Leone – Grubb *et al.* 1998).

Very dark form; hairs along mid-dorsal line without bands; hairs of tail without bands except at tip.

Similar Species

Epixerus ebii. Pelage contains rufous colouration; tail long and bushy, flecked with white.

Protoxerus stangeri. Grizzled white pelage on head and chest; large bushy tail liberally flecked with white.

Distribution Endemic to Africa. Rainforest BZ (Western Region). Recorded from Sierra Leone (near the Liberian border), Liberia, Côte d'Ivoire and Ghana.

Habitat Moist primary rainforests, often associated with *Raphia* palms (G. S. Cansdale in Rosevear 1969). Maybe partly a ground-living squirrel (G. S. Cansdale in Grubb *et al.* 1998).

Allosciurus aubinnii

Abundance Usually rare or uncommon, but may be as common as *P. stangeri* in some moist mature rainforests (Booth 1960).

Remarks One stomach contained the husks of *Raphia* palms (G. S. Cansdale in Rosevear 1969). Probably solitary.

Conservation IUCN Category: Data Deficient.

Measurements

Allosciurus aubinnii

HB: 240 (230–250) mm

T: 298 (270–310) mm

HF: 58 (55–61) mm

GENUS *Atlantoxerus*

Barbary Ground Squirrel

Atlantoxerus Forsyth Major, 1893. Proc. Zool. Soc. Lond. 1893: 139. Type species: *Sciurus getulus* Linnaeus, 1758.

The genus *Atlantoxerus* was originally a subgenus of *Xerus*, and later raised to full generic rank by Thomas (1909c). Closely related to *Xerus*, it presently comprises only one species, which occurs in NW Africa, originally described as *Sciurus getulus*. The single species in the genus mainly inhabits rocky areas in semi-arid and arid regions where they rely on natural shelters or self-dug burrows to escape the extremes of climate. Placed in the Tribe Xerini (together with *Xerus*, the only other genus of ground squirrels).

Barbary Ground Squirrels are medium-large squirrels with a striking bushy tail, relatively large eyes and small ears (without hair brush). The head tends to be blunt and round, with powerful muscles. The nostrils are narrow and naked, and can be closed by the tip of the muzzle. In contrast to other Palearctic ground squirrels, the skull is not angular, has a strong sagittal crest, and the palate extends posteriorly to the cheekteeth. The hindfeet have naked soles and slender digits. The claws, adapted to digging, are long and only slightly curved. Most features are similar to those of the genus *Xerus*, but the fur is not as bristly, although it is short and stiff. Dental formula: $I^{1/1/}, C^{0/0}, P^{2/1}, M^{3/3} = 22$. The skull is characterized by two upper premolars (P^3 is minute, sometimes absent) on each side of the upper jaw, each upper incisor frequently has traces of a groove, and molar surfaces are slightly concave with transversal ridges (M^1 and M^2 are lacking mesostyle, lower molars without anteroconid), palate long (ca. 62% of GLS) with the posterior end of bony palate well posterior to M^3 (as in *Xerus* and unlike other sciurids); masseteric tubercle very prominent (Figure 9). The baculum is long and narrow, ends in a spatulate enlargement with a small crest above and a larger one, bent to the left, below (Cabrera 1932).

Atlantoxerus getulus.

The genus *Atlantoxerus* was first identified with certainty from the early Miocene of China (Li & Qiu 1980, Qiu *et al.* 1999) and middle Miocene of Arabia (Sen & Thomas 1979). Later, it differentiated and spread quickly over southern Europe (Spain; Pelaez-Campomanes 2001), North Africa (Morocco; Lavocat 1961) and eastern Asia (China; Wu 1988). In the upper Miocene, at least four species are known from Spain (De Bruijn & Mein 1968), France (Aguilar *et al.* 1995), Algeria (Ameur 1988), Morocco (Geraads 1998) and Rhodes (De Bruijn *et al.* 1970). In Morocco, several specimens related to *A. getulus* have been reported from the lower and middle Pleistocene (Jaeger 1975, Michel 1990). However, the origin of *A. getulus* (the only extant species of the genus) remains unknown; it does not seem to be a descendant of any known extinct species of the genus that were present in the Maghreb at earlier periods. Jaeger (1977a) suggested a close relationship with the Spanish fossil-form *A. androveri* (De Bruijn & Mein 1968). Additional fossils from the Pliocene are needed to clarify the evolution of the genus, as well as genetical studies on the tribe Xerini to elucidate the relationships of the various genera.

Stéphane Aulagnier

Figure 9. Skull and mandible of *Atlantoxerus getulus* (BMNH 22.5.30.20).

Atlantoxerus getulus BARBARY GROUND SQUIRREL

Fr. Ecureuil fouisseur de Barbarie; Ger. Nordafrikanischer Erdhörnchen (Atlashörnchen)

Atlantoxerus getulus (Linnaeus, 1758). Syst. Nat., 10th edn., 1: 64. 'in Africa'. Restricted by Thomas (1911) to 'Barbary', and by Cabrera (1932) to Agadir, Morocco.

Taxonomy Originally described in the genus *Sciurus*. Synonyms: *praetextus*, *trivittatus*. Subspecies: none. Chromosome number: $2n = 38$, $aFN = 68$.

Description Medium-sized ground-dwelling squirrel with a short pale greyish-brown dorsal pelage and three pale stripes along the body. Pelage short (ca. 3–5 mm) and slightly coarse. Dorsal pelage greyish-brown; hairs pale brown or pale buff terminally, sometimes with black tip. Long black guard hairs, especially on mid-back and rump. Single white side-stripe on each flank from behind shoulders to mid-rump (not to base of tail), bordered on each side by darker background colouration. Single less obvious pale stripe on mid-dorsal line, shorter in length than white side-stripes on flanks. Elongated patch of whitish hair on lower flank between limbs. Ventral pelage sparse; hairs white, sometimes grey at base. Head is rounded and similar in colour to back. Ears small, eyes with narrow pale eye-ring. Limbs moderately long, similar in colour to body. Forefoot with four long digits, each with sharp claw; Digit 1 reduced to small tubercle without claw. Hindfoot with five digits; Digit 1 short; all with long curved claws. Tail of moderate length (ca. 80% of HB), hairs long (ca. 25–30 mm), creamy-white with two wide black bands equidistant along length of hair giving a black–white banded pattern; tip white. Young differ from adults by having longer and smoother pelage. Skull: cheekteeth $5/4$; P^3 very small and peg-like, sometimes absent; posterior end of bony palate well posterior to M^3 ; masseteric tubercle prominent. Nipples: $1 + 1 + 1 + 1 = 8$.

Geographic Variation None recorded.

Similar Species

Xerus erythropus. Dorsal pelage brown, harsh, marked with a single short stripe on each side; muzzle longer with a projecting nose; distribution overlaps only in the Souss plain (Morocco) (Blanc & Petter 1959).

Distribution Endemic to NW Africa. Mediterranean Coastal BZ. Recorded in Morocco and a small area of NW Algeria (Ksours Mts); known from the coastal zone up to 4165 m, mainly in the Middle and Grand Atlas south to Agadir, the Anti-Atlas, and the northern edge of the western Sahara south to Sequiat el Hamra. Introduced (extraliminally) to Fuenteventura (Canary Is.) in 1965.

Habitat Stony regions and open habitats, from mountain slopes to desert. Common in open country with scattered trees and bushes of Juniper *Juniperus* spp., Thuya *Tetraclinis articulata* and Argan *Argania spinosa*, but avoiding areas devoid of vegetation and forests. Also present in various agricultural habitats, favouring stone walls, which provide refuge. Not recorded in irrigated fields.

Abundance Abundant on the lower slopes and valleys. Very common up to 2000 m in the Grand Atlas; but then becoming less

Atlantoxerus getulus

common with increasing altitude. Population numbers also decrease dramatically in the eastern part of the range. Maybe locally numerous in some desert habitats. Fluctuations of population numbers are suspected; for example, they were very numerous in 1952 and rare in 1971 in the same region (Saint Girons 1974).

Adaptations Diurnal and terrestrial. Exhibits two periods of activity: in the morning from 07:00h to 11:00h with a peak of activity at about 09:00h, and in the afternoon from 14:00h to 18:00h with a peak at 15:00h. Optimal temperature for activity is 24 °C. The activity rhythm observed in the Toubkal massif was similar to that at Ademine forest and Jbel Bani at lower altitudes (Petter & Saint Girons 1965). Shelters in burrows during the night and during the heat of the day. Burrows are excavated under rocks, or among stones in screes that have been consolidated by vegetation. Requires permanent water in the southern part of its distribution. At high altitudes, daily activity is reduced greatly during winter, even in the absence of snow cover. True hibernation has not been recorded.

Foraging and Food Mainly herbivorous, sometimes omnivorous. Forages on acorns, nuts and seeds, including those of Argan, but also fruits of wild olive-trees *Oliva europaea*, Juniper and Thuya (Cabrera 1932), and fruits and seeds of Pistachio trees *Pistacia atlantica*. The diet may also include grasses and roots (Carpentier 1932), and also domestic crops, where fallen seeds and stems are eaten (Brosset 1960). Occasionally feeds on insects (Cabrera 1932), and on rubbish in small villages.

Social and Reproductive Behaviour The simplest family unit is composed of a single ♀ with her young. Two ♀♀ with their litters may share a common shelter, at least when the young are able to move around the shelter independently. Pairs of ♀♀ are common before the reproductive season, and sharing of a common natal nest is suspected. These family units may form loose colonies. More complex social groups, including at least three lactating ♀♀ with their young and an adult ♂ have been observed (Gouat & Yahyaoui 2001). Group composition differs greatly (especially during the reproductive season), even between sites that are geographically close together. During the mating period ♂♂ usually stand on a prominent site during the day and call for ♀♀. Several ♂♂ can court one ♀, chasing each other. Records of matings are very rare, and matings are suspected to occur in burrows.

Reproduction and Population Structure Reproductive season varies geographically. Females pregnant in E Morocco in April (Brosset 1960), by which time young have already been born in Saharan Atlas (Cabrera 1932) and young have been weaned in Western Sahara (Valverde 1957). At higher altitudes (Middle Atlas, Grand Atlas, Anti-Atlas), young born in July. Two litters/year may be possible in the Tazenakht region (Anti-Atlas). Litter-size: up to four; in Canary Is., litters of up to nine have been recorded. Young weigh 6–9.5 g at birth, and they leave the burrow when 5–6 weeks old. Captive animals have lived for five years.

Predators, Parasites and Diseases Main predators are diurnal raptors (occasionally owls), and also foxes and genets. Many parasites have been collected (Dollfus 1953, Hastriter & Tipton 1975); the louse *Neohematopinus pectinifer* is reported to carry spirochetes, causing relapsing fever in humans (Blanc *et al.* 1933).

Conservation IUCN Category: Least Concern. Widespread within its range, and not threatened.

GENUS *Epixerus* Western Palm Squirrel

Epixerus Thomas, 1909. *Ann. Mag. Nat. Hist.*, ser. 8, 3: 472. Type species: *Sciurus wilsoni* Du Chaillu, 1860 (= *Sciurus ebii* Temminck, 1853).

Epixerus contains a single species distributed in the Rainforest BZ of West and Equatorial Africa. The genus is distinguished by its large size, long hindfoot (usually over 55 mm) and tapered bushy tail with strongly banded hairs that produce a splendid pattern of chevrons when spread and viewed from below. Skull characteristics are large size (>65 mm), palate extends well posteriorly to the posterior end of M³, ratio of palatal length to interorbital breadth is 56.0% to 65% (Amtmann 1966), masseteric tubercle absent or not prominent, and supraorbital ridge has a foramen (Figure 10). Dental formula: I¹/₁, C⁰/₀, P¹/₁, M³/₃ = 20. Additional characters are given in the species profile.

The number of species in the genus is debatable. Two species are sometimes recognized (e.g. Verheyen 1959, Hoffman *et al.* 1993): *E. wilsoni* (du Chaillu, 1860), with a subspecies *E. w. mayumbicus*, and *E. ebii* (Temminck 1853), with two subspecies *E. e. ebii* and *E. e. jonesi*. Kuhn (1964) revised the genus and, on the basis of a large geographic sample, recognized a single species, *E. ebii* (see also Amtmann 1966, Thorington & Hoffman 2005). Here, a single species, *E. ebii*, is recognized.

Epixerus ebii WESTERN PALM SQUIRREL

Fr. Écureuil des palmier; Ger. Westliches Palmenhörnchen

Epixerus ebii (Temminck, 1853). Esquisses zoologiques sur la côte de Guinée, p. 129. 'Les grandes forêts de la Guinée'. Ghana.

Taxonomy Originally described in the genus *Sciurus* (see also genus profile). The form *wilsoni* was formerly considered as a distinct species (e.g. by Perret & Aellen 1956, Verheyen 1959 and Rosevear 1969), but is here considered as a subspecies. Synonyms: *jonesi*, *mayumbicus*, *wilsoni*. Subspecies: three. Chromosome number: not known.

Description Very large, reddish, slender-bodied squirrel with long legs and long, bushy, grey-frosted tail. Pelage short. Dorsal pelage dull brownish-red, finely grizzled with yellow and black. No side-stripes on flanks. Ventral pelage sparse with some whitish hairs on chest; yellow ventral skin sharply delineated from lateral pelage. Head large and broad, with large eyes; ears relatively large, naked, extending above crown. Bulging cheeks (due to large highly developed masseter muscles). Limbs and feet long and slender, similar in colour to dorsal pelage. Tail long (ca. 95% of HB), bushy, tapered at tip, frosted grey, with indistinct alternating bands of blackish and pale grey. Alternating bands of red, black and grey on the tail hairs create a pattern of chevrons on the underside of the tail when hairs are spread and viewed from below (not normally visible in the field). Tail carried horizontally, straight out behind the body, or hanging, not curled up against back. Skull: cheekteeth $4/4$; posterior end of bony palate posterior to M^3 ; masseteric tubercle not prominent. Nipples: $1 + 1 + 1 + 1 = 8$; one specimen with five pairs = 10 was reported in Liberia (Kuhn 1964).

Geographic Variation

E. e. jonesi: Liberia and Sierra Leone. Head and dorsal pelage rufous.

E. e. ebii: Ghana and Côte d'Ivoire. Head rufous, dorsal pelage browner.

*Epixerus ebii**Epixerus ebii*.

E. e. wilsoni: Cameroon, Gabon, Equatorial Guinea and Congo. Head and dorsal pelage reddish-brown.

Similar Species

Protoxerus stangeri. Larger, greyer, with stout body, long back, short robust legs; head grizzled grey; short ears that do not extend above crown; arboreal.

Distribution Endemic to Africa. Rainforest BZ (Western and West Central Regions). Recorded from Liberia and Sierra Leone to Ghana; S Cameroon, Gabon, Equatorial Guinea and Congo.

Habitat Evergreen rainforests. Undergrowth in forest, including *Raphia* palms. In Sierra Leone, recorded from montane forest at 1020 m (Grubb *et al.* 1998).

Abundance Rare in collections and rarely seen; but in Gabon it is more common than usually supposed. Its terrestrial habits, extreme wariness and tendency to escape silently on the ground at the slightest disturbance, allow it to exist undetected by Western naturalists (who often mistake it for a Forest Giant Squirrel *Protoxerus stangeri*). None the less, local peoples who hunt game with nets know this species well and have specific names for it. The very short activity period (see below) may contribute to the perceived rareness of these squirrels.

Adaptations Diurnal. A cursorial, fast-running terrestrial species with elongated, slender limbs and feet, and a slender lower abdomen;

sometimes assumes a digitigrade posture with forelimbs bearing weight only on the tips of the digits. The masseter muscles are highly developed and the incisors are robust, consistent with a diet of kernels from hard nuts. A prominent glandular pocket in the inside corner of the lips may be used in scent marking (Emmons 1975, 1980).

Western Palm Squirrels make dens in tree hollows and favour those hollows with small entrances (mean height: 8.1 m [1.5–20 m]; $n = 12$ den sites; Emmons 1975). The nest itself is undescribed. They leave the nest at dawn; in Gabon they have a short activity period (mean 7.69 h) and return to the nest in the late afternoon or well before dusk (mean entry time 14:50h; range: 12:30–17:03h, $n = 16$; Emmons 1980). Climbing to the nest is their only arboreal activity.

Foraging and Food Feeds terrestrially on fallen seeds and fruit, especially on thick-walled nuts (98% dry mass, $n = 4$ stomach contents; Emmons 1980). A few insects are also consumed. To feed on nuts it jumps up from the ground onto a low feeding perch (0.5–1.5 m), probably to scan for predators while deafened by gnawing. In Gabon, feeds mostly on nuts of *Panda oleosa*, a large, elephant-dispersed fruit. The presence of this squirrel in an area can be readily ascertained by the presence of large middens of shells from opened *Panda* nuts beneath low perches: the seeds are extracted by either splitting along the lines of dehiscence (old nuts) or by the extraordinary feat of ‘sawing’ nuts in half across the middle (fresh nuts). No other animal opens *Panda* nuts by this method. Western Palm Squirrels hoard *Panda* nuts by burying them in the ground at distances of 15–20 m or more from the parent tree (Emmons 1975), thereby assisting the dispersal of the seeds.

Social and Reproductive Behaviour In 50 observations, squirrels were solitary 80% of the time and seen with 1–3 others in the remainder of sightings (Emmons 1980). Two adults feeding under the same *Panda* tree tolerated each other and showed no aggression. Two adult ♂♂ followed by radio-tracking in Gabon had home-ranges of 21.1 ha and 21.7 ha, and a single subadult ♀ had a home-range of 13.9 ha. Movement is rapid: ♂♂ travel at a mean rate of 115 m/h and ♀♀ at 144 m/h (means of all hours when active). The social organization is unknown, but in one apparent ‘mating chase’ several calling ♂♂ pursued a presumably oestrus ♀ (Emmons 1980).

Vocalizations are described in detail in Emmons (1978). The low intensity alarm call consists of soft, short (about 400 ms), rapid, machinegun-like bursts of chattering of the incisor teeth. High intensity alarm is indicated by a staccatto series of short, broad-frequency pulses. When alarmed, a squirrel may climb to a low vantage point on a horizontal or vertical support, with the long bushy tail hanging straight downward. At the start of each high intensity alarm call, the base of the tail is wagged rapidly and vigorously from side to side a few times, the tail-tip following passively, whipping loosely back and forth below the body. Squirrels calling from the ground hold the tail horizontally, with no wagging display.

Reproduction and Population Structure The only published litter-size is 2 ($n = 1$, Emmons 1979a).

Predators, Parasites and Diseases Sometimes captured by local people in hunting nets.

Conservation IUCN Category: Least Concern. Likely to be threatened only by loss of mature rainforest. Home-ranges are large so that the density of squirrels is always relatively low.

GENUS *Funisciurus*

Rope Squirrels

Funisciurus Trouessart, 1880. Le Naturaliste 2 (37): 293. Type species: *Sciurus isabella* Gray, 1862.

A genus of small- to medium-sized squirrels with ten species endemic to the Rainforest BZ and parts of the adjacent Rainforest–Savanna Mosaics (Table 11). The greatest diversity is in west-central Africa, with five species in Cameroon. Most species are arboreal; some species live in the canopy in natural rainforest, and others live in tangled vegetation close to the ground and in secondary growth. A few species enter plantations and gardens. The vernacular name ‘Rope Squirrel’ refers to the ability of these squirrels to clamber and climb on rope-sized branches and lianas. An alternative vernacular name ‘African Striped Squirrel’ refers to the lateral side-stripe(s) on each flank.

The genus is characterized by relatively small size (mean HB usually 130–200 mm), long well-haired tail slightly shorter than the head and body, and (in most species) a longitudinal side-stripe along each flank. The species of the genus are the smallest of African squirrels, except for the single species of *Myosciurus* (HB 61–74 mm). The head is small, with small ears held close to the skull; the limbs are short, and the long tail is covered with long hairs that are held erect to give a bushy appearance. The tail is commonly held upwards and backwards, close to the back with the tip curling away from the shoulders; it is constantly flicked backwards and forwards as a means of

Funisciurus squirrels.

communication and when the squirrel is agitated. Females have either two pairs of nipples (most species) or four pairs (*F. leucogenys*). Rope Squirrels produce a range of vocal noises, including clicks, squeaks and chatters.

The skull is characterized by the dental formula $I \frac{1}{1}, C \frac{0}{0}, P \frac{2}{1}, M \frac{3}{3} = 22$; orange ungrooved incisors, five (not four) cheekteeth in

each upper ramus (cf. *Heliosciurus*); small masseteric tubercle; fossa for origin of anterior deep masseter muscle does not extend onto the rostrum; supraorbital foramen absent; and the posterior end of the bony palate is approximately in line with the posterior end of M^3 (in this latter respect it is similar to several other genera of squirrels but different from *Atlantoxerus*, *Xerus* and *Epixerus* where it

Figure 11. Skull and mandible of *Funisciurus anerythrus* (BMNH o.2.5.33).

is posterior to M^3). Cusps of cheekteeth are worn down early in life, leaving flattened surfaces (not concave with prominent ridges as in *Heliosciurus*) (Figure 11).

The genus exhibits considerable diversity in morphology, especially in colour and in the form of the lateral side-stripe. Species in the genus range from small black-striped squirrels to somewhat larger squirrels with successive reduction of the stripes on each side. The gradual reduction in number and size of the side-stripes is illustrated in the following sequence: (a) *F. isabella*, *F. lemniscatus* (smaller species; two black stripes); (b) *F. congicus* (smaller species; stripe pattern slightly modified to a blackish-brown side-stripe bordered by a cream stripe); (c) *F. bayonii*, *F. substriatus* (relatively small species; stripes reduced to a pale lateral side-stripe); (d) *F. pyrrhopus*, *F. anerythrus* (larger species, reddish pigment in many subspecies; pale side-stripe, often rather obscure); (e) *F. leucogenys* (largest; stripes reduced to line of whitish spots); and (f) *F. carruthersi* (relatively large, no side-stripe). See Rosevear (1969) for a full discussion of the genus.

The genus is placed in the subfamily Xerinae and tribe Protoxerini (which also includes all the other African sciurids except *Atlantoxerus* and *Xerus* – the Ground Squirrels – which are placed in the tribe Xerini) (Thorington & Hoffman 2005).

Species in the genus are distinguished by colour, number and character of the lateral side-stripes, colouration of body and limbs, and body and skull size (Table 11).

Peter Grubb

Table 11. Species in the genus *Funisciurus*. Arranged in order of increasing number of side-stripes on each flank.

| Species | Side-stripes on each flank | Red colouration on pelage | General colouration | HB mean (mm) | HF mean (mm) | GLS mean (mm) | Notes |

***Funisciurus anerythrus* THOMAS'S ROPE SQUIRREL (REDLESS TREE SQUIRREL)**

Fr. Funisciure de Thomas; Ger. Rotloses Baumhörnchen

Funisciurus anerythrus (Thomas, 1890). Proc. Zool. Soc. Lond. 1890: 447, pl. 40. Buguera, south of Lake Albert, Uganda.

Taxonomy Originally described as a subspecies of *Sciurus pyrrhopus* in 1890 and later raised to specific rank. There has been great confusion about the taxonomic placement of the named subspecific forms of *F. anerythrus* and *F. pyrrhopus*; several subspecies have ping-ponged back and forth between the two species. In Gabon, where the local forms of the two species are sympatric, they are unequivocally distinguished by their physical characters and their entirely distinctive calls, as well as by major ecological differences in habitat, diet and nest sites (Emmons 1975, 1980). These distinctions, described below, should be considered when assigning West African forms to one of these two species. Synonyms: *bandarum*, *mystax*, *niapu*, *ochrogaster*, *raptorum*. Subspecies: four. Chromosome number: $2n = 38$, $FN = 62$ (Benin, Civitelli *et al.* 1996).

Description Medium-sized plain brown squirrel with a pale side-stripe from shoulder to rump. Dorsal pelage grizzled brown flecked with buff; hairs banded. Single pale buff side-stripe from shoulder to hindquarters, bordered below with dark brown. Ventral pelage thickly haired, dull grey to white or orange. Head similar to dorsal pelage. Eye bordered above and below with pale buff line. Ears small. Fore- and hindlimbs dull buff; digits with well-developed claws. Tail medium (ca. 85% of HB – relatively short for a squirrel), hairs long, banded reddish at base, black distally, white at tip. Tail appears reddish medially when viewed from below, and from above it is dark with white frosting. Tail carried curled up against back when squirrel is at rest; often held high, with the base vertical and tip curled backward when squirrel is moving. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent (and often barely visible). Nipples: $0 + 0 + 2 + 2 = 4$.

Geographic Variation Four subspecies were recognized by Amtmann (1966):

F. a. anerythrus: W Uganda and DR Congo south to Mt Kabobo. Dorsal pelage reddish-brown, ventral pelage ochraceous.

F. a. bandarum: Central African Republic. Dorsal pelage buff-tinged, ventral pelage pale grey to orange.

F. a. mystax: S Cameroon to Gabon. Dorsal pelage warm brown, ventral pelage orange.

F. a. raptorum: SW Nigeria. Dorsal pelage grey-tinged, ventral pelage whitish.

Amtmann (1966) placed far western forms (e.g. *mandingo*; Sierra Leone), previously attributed to this species, in *F. pyrrhopus*.

Similar Species

Funisciurus pyrrhopus. Larger (HB: 190–230 mm); longer nose; limbs bright to dull reddish; ventral pelage white.

Distribution Endemic to Africa. Rainforest BZ (West Central, East Central and South Central Regions) and surrounding forest–savanna mosaics. Recorded from Benin, Nigeria, Cameroon,

*Funisciurus anerythrus*

Equatorial Guinea, S Central African Republic, Gabon, DR Congo and Congo.

Habitat Permanently or seasonally flooded waterside habitats of swamps, gallery forests, seasonally flooded riversides, and islands in rivers. Especially abundant in *Raphia* palm swamps. In Gabon, it is not found in terra firma forest even where this abuts directly on riversides (Emmons 1975, 1980). In Nigeria, prefers lower strata of secondary forest and tangled vegetation where there is a dense growth of shrubs and creepers; may also be seen climbing in medium-sized trees and oil palms (Happold 1977).

Abundance Common in suitable habitats, where it can reach higher densities than does any other species of African tree squirrel.

Adaptations Diurnal and scansorial. Forages on the ground and at all levels within the low-canopy of seasonally flooded forests (mean height: 3.8 m [1–13 m], $n = 20$). Builds round nests (20–24 cm diameter) of leaves lined with fibres. In habitats dominated by *Raphia* palms, the outer shell of the nest is often built with palm leaflets. The nests are exposed, but partially hidden in dense clumps of vegetation in the branches of trees or on the rachis of palm leaves. Most nests are built in vegetation that overhangs water (Emmons 1975).

Foraging and Food Omnivorous. Feeds on fruits and seeds (77% dry mass of stomach contents in Gabon, $n = 15$), arthropods (20%) and minor amounts of green plant tissues and mushrooms. In *Raphia* palm swamps, these squirrels feed intensively on the orange pericarp

of *Raphia* fruits, and they can be seen feeding and climbing around in the crowns of palms. They temporarily cache these palm nuts by wedging them into above-ground crevices. The arthropod portion of the diet is dominated by ants (92% occurrence) and termites (58% occurrence), but many other taxa are also eaten (Emmons 1980).

Social and Reproductive Behaviour These squirrels often live in dense populations, and in Gabon were seen with other conspecifics 50% of the time ($n = 431$ observations). Individuals travelling in pairs (28% of observations) followed each other closely, groomed each other, and rested in contact. Up to six individuals were seen feeding at the same fruit tree. A captive heterosexual pair shared a nest box and showed contact behaviour, but competed aggressively for food (Emmons 1980). The social organization is unknown, but the above observations are consistent with monogamous pair formation.

Vocalizations are common (see Emmons 1978 for details). The low intensity alarm call consists of frequency-modulated chucks emitted in groups of 1–6, but usually singly (45% of 166 call bouts). The high intensity call is an astonishing sound unlike that of any other species: a long series of stereotyped groups of 2–4 rhythmic pulses followed by 1–2 long, low frequency whistles (dada dada dadada . . . dadaweeeeeeou). Only the final whistles can be heard at a distance. During a low intensity alarm call, the tail is jerked sharply downward from its resting position against the back, then slowly returns up to its normal posture. As the tail is flicked down, the hindfeet are simultaneously stamped on the substrate, followed by stamping of the forefeet as the tail is raised.

Reproduction and Population Structure Embryo number: 1.2 (1–2, $n = 77$ litters; Rahm 1970) in E DR Congo, and 1.5

(1–2, $n = 6$; Dubost 1968, Emmons 1979a) in Gabon. In E DR Congo, pregnancies occur in all months of the year, with the highest pregnancy rate at the end of the dry season and beginning of the wet season (Aug–Oct) (Rahm 1970).

Predators, Parasites and Diseases These squirrels have been implicated as hosts for the monkeypox virus (Jezek & Fenner 1988).

Conservation IUCN Category: Least Concern.

Its widespread distribution and commonness in many habitats would suggest that the appropriate category is Least Concern.

Funisciurus bayonii LUNDA ROPE SQUIRREL

Fr. Funisciure de Bocage; Ger. Bocages Baumhörnchen

Funisciurus bayonii (Bocage, 1890). Jornal de Sciencias Mathematicas Physicas e Naturaes da Academia de Lisboa, ser. 2, 2: 3. '... du Duque de Bragança'. N Angola (exact locality not known).

Taxonomy Originally described in the genus *Sciurus*, but reallocated on the basis of skull characters to *Funisciurus* by Hayman (1951). Synonyms: none. Chromosome number: not known.

Description Small to medium-sized dark squirrel with indistinct white side-stripe. Dorsal pelage uniformly dull olive, speckled with black. Indistinct side-stripe from shoulder to rump, buff to whitish-buff. Ventral pelage grey tinged with buff. Upper surface of head, fore- and hindlimbs similar to dorsal pelage. Pale eye-ring. Tail long (ca. 100% of HB), grizzled, black and ochre without obvious rings, darker than body. Skull: short muzzled, resembling *F. congicus* in this respect; postorbital processes well developed; nasals broad; cheekteeth 5/4; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: not known.

Geographic Variation None recorded.

Similar Species

F. congicus. Paler, also with side-stripe; probably not sympatric.

Funisciurus bayonii

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded from NE Angola and SW DR Congo south of Kasai and Congo rivers.

Habitat Uncertain. According to Amtmann (1966), who based his conclusions on a vegetation map of the species range, the habitat is probably moist forest at low to medium elevations; and forest–savanna mosaic, woodland and savannas in south-western parts of the range (principally on Kalahari Sand).

Abundance No information. Known only by a few specimens.

Remarks Apparently no other information.

Conservation IUCN Category: Data Deficient.

Funisciurus carruthersi CARRUTHERS'S ROPE SQUIRREL (CARRUTHERS'S MOUNTAIN SQUIRREL)

Fr. *Funisciure de montagne*; Ger. Carruthers Baumhörnchen (Bergstreifenhörnchen)

Funisciurus carruthersi Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 140. 'Rwenzori East, 6500 ft' (= 1900 m), Uganda.

Taxonomy *Funisciurus carruthersi* appears to straddle a taxonomic boundary in sharing characteristics of both the Rope Squirrels *Funisciurus* and Bush Squirrels of the *Paraxerus lucifer/byatti* complex. In common with *Funisciurus* spp., adults have flat-crowned upper and lower cheekteeth. By contrast, the colouring, body size and ecological habits of *F. carruthersi* appear to ally it more closely with *Paraxerus*. Hopefully, molecular studies will help shed some light on an ambiguous taxonomic situation. Synonyms: *birungensis*, *chrysippus*, *tanganyikae*. Subspecies: three. Chromosome number: not known.

Description Medium to large soft-furred olive-green squirrel with grey ventral pelage. Dorsal pelage grizzled olive-green and black, darker on mid-dorsal line; hairs long and soft, dark grey or black at base, yellowish-buff or olive-green subterminal band, and black tip. Long black guard hairs, especially on mid-dorsal line. Flanks paler, with fewer black-tipped hairs, and without side-stripes. Ventral pelage from throat to tail grey or greyish-white; hairs medium-grey at base, white or greyish-white at tip. Scrotum olive-green, as flanks. Head and cheeks similar to dorsal pelage. Conspicuous creamy-yellow eye-ring. Ears small, pigmented, with sparse short hairs, and with sharply angled leading edge (so overall shape intermediate between the rather rectangular ear of *Funisciurus* and more rounded ears of *Paraxerus*). Forelimbs with four digits; hindlimbs with five digits (Digit 1 reduced); all digits have a strong sharp claw. Colour of pelage of limbs fades to brown before the moult. Tail long (ca. 100% of HB), ochre and black, with inconspicuous bands along length; hairs long, ochre at base, with black subterminal band and ochre at tip. Skull: cheekteeth ⁵/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 1 + 2 = 6.

Geographic Variation Amtmann (1966) lists the following subspecies:

Funisciurus carruthersi

F. c. carruthersi: Rwenzori Mts.

F. c. birungensis (including *chrysippus*): Mountains of SE Uganda, E DR Congo, Rwanda and NW Burundi.

F. c. tanganyikae: Mountains around north end of L. Tanganyika.

Similar Species

Heliosciurus ruwenzori. Similar size; dorsal pelage grey, ventral pelage white; tail with grey and white bands.

Heliosciurus rufobrachium. Similar size; pelage of limbs reddish or rufous; tail with conspicuous black and white bands.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from the montane forests of the Rwenzori Mts and Albertine Rift Valley mountains in E DR Congo, Uganda, Rwanda and Burundi (Thorington & Hoffman 2005). Altitude range: 1500–2800 m.

Habitat Montane forests, especially in stands of *Prunus* (*Pygeum*) *africanum*, a common tree species in the region and, at the upper reaches of its altitudinal range, in forests of *Hagenia abyssinica*. Prefers areas of forest with a broken canopy where trees are smothered in climbers, and undergrowth is densely tangled. Does not adapt well to cultivated areas. In E DR Congo most observations were close to rivers (Rahm & Christiaensen 1963).

Abundance Uncertain. Apparently common in all *Prunus africanum* stands throughout their range. Supposedly less common in higher reaches of montane forest. Abundance is difficult to assess because these squirrels are very shy and inhabit dense vegetation.

Adaptations Diurnal and arboreal. Carruthers's Mountain Squirrels are unusual among squirrels at higher altitudes in becoming active shortly after dawn as well as in the evening. They are less conspicuous than Sun Squirrels *Heliosciurus* living in the same habitat. The drab-coloured tail, in particular, which is commonly carried over the back, is less conspicuous, even when waved about. This suggests that the principal function of tail flicking is dispersion of scent from the anal glands. There may therefore be a bias in this species towards communication by olfactory rather than by visual signals. Their olive-green colouring provides well-matched camouflage on leafy branches and on the mossy, lichened trunks and branches of trees. Their colouring and noteworthy shyness may reflect greater vulnerability than Sun Squirrels to the abundant buzzards, hawks and hawk-eagles found in montane habitats.

Foraging and Food Primarily frugivorous. Foraging occurs at all levels, even, rarely, on the ground. Recorded as feeding on the fruits of *Bridelia* spp., *Alchornea* spp., *Carapa grandifolia* and *Strombosia scheffleri* and the fruits of an unnamed gourd (Rahm & Christiaensen 1963). Traces of insects have been found in stomachs but very fine

mastication has prevented accurate identification of plant foods (Kingdon 1974).

Social and Reproductive Behaviour Usually seen singly, occasionally in pairs. They have been heard to make a rasping, quacking cry, possibly an advertising or contact call, but its significance has not yet been determined. Reported to make large nests of plant material in liana tangles; these are lined with finely shredded bark torn from a local shrub (Kingdon 1974).

Reproduction and Population Structure Very little information. There is a single record of a lactating ♀ from SW Uganda in May (Kingdon 1974). An absence of records of juveniles suggests young remain well concealed.

Predators, Parasites and Diseases Likely predators are hawk-eagles *Hieraaetus africanus* and *H. dubius*, eagles, buzzards and, more rarely perhaps, genets and Golden Cats *Profelis aurata* (Kingdon 1974).

Conservation IUCN Category: Least Concern. Previously considered as Vulnerable.

Funisciurus congicus CONGO ROPE SQUIRREL (STRIPED TREE SQUIRREL)

Fr. Funisciure du Congo (Funisciure de Kuhl); Ger. Kongo Baumhörnchen

Funisciurus congicus (Kuhl, 1820). Beiträge zur Zoologie und vergleichenden Anatomie 2: 66. 'Congo'; no specific locality given, probably Angola (Hill & Carter 1941).

Taxonomy Originally described in the genus *Sciurus*. Seven subspecies have been described, but Amtmann (1975) considered them invalid because geographic variation in size and colouration is highly correlated with temperature and rainfall (Amtmann 1966). *Funisciurus poolii* included in this species by Amtmann (1975). Synonyms: *damarensis*, *flavinus*, *interior*, *oenone*, *olivellus*, *poolii*, *praetextus*. Subspecies: none. Chromosome number: not known.

Description Small brown squirrel with long wide side-stripes. Pelage short and soft. Dorsal pelage grizzled yellowish-brown; hairs

black at base, yellowish-brown terminally, some with black tip. Each flank with wide white or cream side-stripe from shoulder to rump, and narrow pronounced brownish-black stripe below the white stripe. Ventral pelage white. Crown of head brown, cheeks and throat white. White stripes above and below eye, forming incomplete eye-ring; stripes buff or pale ochre on specimens from northern Angola. Ears with white, buff, or pale ochre hairs on outer margins. Outer surface of limbs buff, inner surface white. Tail long (ca. 105% of HB), thin and bushy, black and buff above, pure white below; hairs black at base with alternating bands of buff and black, buff tip above,

Funisciurus congicus

white below. At rest, tail held along surface of back, with terminal quarter curled over posteriorly. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: $0 + 0 + 1 + 1 = 4$.

Geographic Variation Pelage varies geographically. Individuals from drier regions have paler colouration; those from more humid areas (e.g. C DR Congo) tend to be dark brownish-black.

Similar Species

F. bayonii. Slightly larger; uniformly dull olive, speckled with black; side-stripe indistinct.

Other *Funisciurus* spp. Darker, often with rufous and rusty colouration.

Paraxerus cepapi. Slightly larger (HB♂: 145–203 mm); pelage grey, yellowish-brown or brown; without side-stripe.

Distribution Endemic to Africa. Rainforest BZ (South Central Region), western parts of Southern Rainforest–Savanna Mosaic, and Zambezian Woodland BZ. Widely but patchily distributed in DR Congo (south of Congo R.), W Angola and NW Namibia.

Habitat Coastal palm groves, mopane woodland and tall forest trees, especially along watercourses and on granite outcrops. Requires denser vegetation than *Paraxerus cepapi*, with which it is sympatric in parts of the geographic range.

Abundance Common. In optimal habitat in Namibia, densities may reach 12–18 animals/ha (Viljoen 1978).

Adaptations Diurnal, arboreal and terrestrial. In Namibia, these squirrels emerge from their nests soon after dawn (from 07:05h to 08:15h, depending on whether the day is clear or overcast) and return to their nests in early evening (18:00–18:50h), well before

sunset. On cool mornings they are especially active, probably in order to generate body heat. During hot days they bask in the sun, and may also hold the white underside of the tail over the back to prevent over-heating. These squirrels are very agile and move easily and quickly, jumping from branch to branch. Observations ($n = 210$) indicate that they prefer habitats on or near the ground: 39% on ground, 42% in subcanopy (<2.5 m) and only 18% in the canopy (>2.5 m above ground) (Viljoen 1978). If disturbed on the ground they immediately flee into the trees. Nests are made in the forks of branches and are constructed of twigs, leaves and grass; sometimes nests are in the holes of trees. When running, the tail is held over the back in the form of a question mark (Viljoen 1978).

Foraging and Food Omnivorous. Foraging takes place on the ground (39% of the time) and in the subcanopy, mostly in trees up to 2.5 m high. The diet includes seeds, fruits, stems and shoots, especially of *Colophospermum mopane*, Velvet Commiphora *Commiphora mollis*, *Grewia bicolor* and other trees. One individual was observed feeding on Mopane Caterpillars *Gonimbrasia belina*. Hard foods may be buried for eating later (Viljoen 1978, Smithers 1983).

Social and Reproductive Behaviour Congo Rope Squirrels are social animals, and live in small groups of up to four individuals. Individuals in the group keep in contact by a series of bird-like high-pitched chirps, and by sight. Individual recognition is by the use of scent, and bonding within the group is maintained by scent and by mutual grooming. The alarm call, in response to a raptor, is a series of high-pitched whistles, which causes other individuals to ‘freeze’ instantly. When a ground predator is spotted, the squirrels emit bird-like chirps accompanied by flicking of the tail; a group may mob a predator by peering down at it while tail-flicking and chattering. Daily home-range of a group living in narrow riverine vegetation (20 m wide on either side of the river bank) is about 0.5 ha; one group moved 200 m on either side of the river during a day, a home-range of ca. 0.4 ha (Viljoen 1978, 1997).

Reproduction and Population Structure Juvenile specimens in museum collections are most common in Apr–Jun and Oct–Jan suggesting two birth seasons/year. Litter-size: 2 ($n = 8$; Viljoen 1978).

Predators, Parasites and Diseases Ectoparasites include two species of ticks (*Haemaphysalis* sp. and *Rhipicephalus* sp.) and one species of flea (*Libyastus vates*). Predators probably include snakes, mammalian carnivores and hawks.

Conservation IUCN Category: Least Concern.

Funisciurus duchaillui DU CHAILLU'S ROPE SQUIRREL

Fr. Funisciure de Duchailu; Ger. Duchailu Baumhörnchen

Funisciurus duchaillui Sanborn, 1953. Mammalia 17: 167. Poingi (01° 39' S, 11° 46' E), Gabon.

Taxonomy Described as a valid species from a single specimen; later placed as a synonym of *F. isabella* (Amtmann 1975, Hoffman *et al.* 1993, Thorington & Hoffman 2005). Reinstated as a full species, separable from *F. isabella*, on the basis of size and ecology by Brugièrè *et al.* (2005). Synonyms: none. Chromosome number: not known.

Description Medium-sized arboreal squirrel with four stripes on back. Dorsal pelage olive-brown. Two side-stripes on either side of mid-dorsal line; black from head to base of tail. Flanks grey to greyish-white; hairs with white tip. Ventral pelage grey; hairs with white tip. Head olive-brown. Limbs, fore- and hindfeet grey. Tail long (ca. 100% of HB), slender, with long hairs. When at rest, the tail is curled over the back and is frequently flicked. Skull: cheekteeth $5/4$. Nipples: not known.

Geographic Variation None recorded.

Similar Species

F. lemniscatus. Smaller (HB mean: 164 mm; GLS mean: 43.6 mm); ventral pelage white or buffy; two side-stripes on each flank from base of neck to rump; more widespread distribution.

F. isabella. Smaller (HB mean: 158 mm, GLS mean: 40.9 mm); ventral pelage grey, white at tip; two side-stripes on each flank from ears/head to rump/base of tail; more widespread distribution.

Distribution Endemic to Africa. Rainforest BZ (West Central region [Gabon subregion]). Recorded from C Gabon, south of the Ogooué R. and south to the Massif du Chaillu. Appears to be allopatric to *F. isabella*.

Habitat Rainforest, especially where trees of the families Cesalpiniaceae and Burseraceae are common.

Abundance Moderately common within its restricted range; comprised 29% of sightings (n = 95; Brugièrè *et al.* 2005), and was the commonest of eight species observed (the second most numerous species was *F. lemniscatus* [22% of observations]).

Remarks Usually seen singly or less frequently in pairs. Mostly observed in the lower storeys of the forest at 4–6 m above ground, but has been recorded in all storeys from ground level to >25 m (mean height: 10.2 m, median height: 6.0 m). When alarmed, escaped along branches or into higher levels of the forest, never along the ground (cf. *F. lemniscatus*) (Brugièrè *et al.* 2005). Observed eating fruits of *Xylopia aethiopica* and *Dialium* sp.

Funisciurus duchaillui

Conservation IUCN Category: Not Evaluated. Probably should be assessed as Data Deficient or Least Concern. Conserved within Lopé National Park, Gabon.

Funisciurus isabella LADY BURTON'S ROPE SQUIRREL

Fr. Funisciure d'Isabella (Funisciure de Gray); Ger. Lady Burtons Baumhörnchen

Funisciurus isabella (Gray, 1862). Proc. Zool. Soc. Lond. 1862: 180, pl. 24. Cameroon Mountain, Cameroon. 7000 ft (2130 m).

Taxonomy Originally described in the genus *Sciurus*. Named after the wife of Sir Richard Burton, the British Consul in Fernando Poo at the time (Rosevear 1969). Taxonomy is reviewed in Amtmann (1966) and Rosevear (1969). The form *duchailui*, placed as a synonym of *F. isabella* by Thorington & Hoffman (2005), is considered as a full species here (see above). Synonyms: *dubosti*. Subspecies: none. Chromosome number: not known.

Description Small brown squirrel with four black side-stripes. Dorsal pelage brown, slightly grizzled with buff; hairs black with buff tips. Two black side-stripes on each flank: inner side-stripe from between ears to base of tail; outer side-stripe from base of neck/shoulder to rump; buffy-brown pelage between all black dorsal side-stripes, but paler than on shoulders. Ventral pelage grey; hairs grey at base, white at tip. Tail long (ca. 100% of HB), slender, with long hairs, buff at base, black distally, with frosted buff tip. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Males tend to be slightly larger than ♀♀. Nipples: $0 + 0 + 1 + 1 = 4$.

Geographic Variation None recorded.

Similar Species

F. lemniscatus. Inner black side-stripes do not extend onto neck; pelage between inner side-stripes is darker (dull brown) than between outer and inner side-stripes (pale yellow).

Distribution Endemic to Africa. Rainforest BZ (West Central Region). Recorded from S Cameroon, Equatorial Guinea (Rio Muni), Gabon, SW Central African Republic and NW Congo. Also Brazzaville, S Congo.

Habitat Lady Burton's Squirrels are found in dense, brushy or viny thickets within the Rainforest BZ. Preferred habitats include dense secondary growth alongside roads, abandoned gardens and plantations, and other habitats with closed vegetation below 5 m (Emmons 1975, 1980). They do not live in tall mature rainforest. In some parts of their range, they share this habitat with *F. lemniscatus*.

Abundance Common where habitat is optimal, but distribution is patchy.

Adaptations Diurnal and scansorial. Forage above the ground (90% of sightings), but generally stay below 10 m in dense thickets and vine tangles where often the most numerous species of squirrel (Emmons 1980). Nests found where there were many *F. isabella*, but no *F. lemniscatus*, closely resembled nests of *F. lemniscatus* in structure and placement (see *F. lemniscatus*). Bates (1905, cited in Rosevear 1969) stated that nests consist of a ball of dry leaves and fibres.

Funisciurus isabella

Foraging and Food Omnivorous. In Gabon, diet is fruits and seeds (81% of dry matter of stomach contents, $n = 14$), green plant tissue (9.2%) and arthropods (6%), with minor amounts of fungi. Arthropods consumed are chiefly ants (79% occurrence), termites (59% occurrence) and lepidopteran larvae (29%) (Emmons 1980).

Social and Reproductive Behaviour Usually seen alone or in pairs, occasionally in threes (69% alone, 21% pairs, 10% threes; $n = 29$ sightings). Two captive ♀♀ shared a nest box and groomed each other (Emmons 1980). There is no detailed information on social organization.

Lady Burton's Squirrels call readily and often (see Emmons 1978 for details). The low intensity alarm call is a series of chucks emitted singly (45% of 71 groups) or in groups of two (41%) to four. The unique high intensity alarm call is a series of linked, frequency-modulated pulses that form a long warbling sound. The most frequent number of warbles in a call is 7 (60% of 95 calls), followed by 5 (30%), but calls may consist of 2–10 warbles. Warbles alternate between shorter (about 160 ms) and longer (about 310 ms) pulses. Each series of warbles may be preceded by 1–14 stereotyped short warbles. Because of the density of their habitat, Lady Burton's Squirrels are more often heard than seen, and their presence is most easily determined by identifying their calls.

Reproduction and Population Structure Litter-size seems restricted to one ($n = 11$; Dubost 1968, Emmons 1979a).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.
Previously considered as Near-Threatened.

Funisciurus lemniscatus RIBBONED ROPE SQUIRREL

Fr. Funisciure rayé; Ger. Streifiges Baumhörnchen

Funisciurus lemniscatus (Le Conte, 1857). Proc. Nat. Acad. Sci. Philadelphia 9:11. Equatorial Guinea (Rio Muni).

Taxonomy Originally described in the genus *Sciurus*. Taxonomy reviewed in Amtmann (1966) and Rosevear (1969). Synonyms: *mayumbicus*, *sharpei*. Subspecies: two. Chromosome number: not known.

Description Small brown squirrel, similar to *F. isabella*, with four black side-stripes on each flank. Dorsal pelage brown, hairs finely banded black and buffy. Two black side-stripes on each flank from base of neck to rump; inner side-stripes separated by dull brown (on mid-dorsal line); outer side-stripe separated from inner side-stripe by pale yellow pelage. Ventral pelage white or buffy. Tail long (ca. 80% of HB), bushy, with banded hairs, grizzled buff and black, with yellowish-buff below. Tail curled up over the back when the squirrel is at rest. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 0 + 0 + 1 + 1 = 4.

Geographic Variation Two subspecies were recognized by Amtmann (1966) and Thorington & Hoffmann (2005):

F. l. lemniscatus: north of Ogoué R., Gabon. Ventral pelage white.

F. l. mayumbicus: south of the Ogoué R., Gabon. Ventral pelage buffy.

Similar Species

F. isabella. Slightly smaller (HB ♂ ♂: 158 [150–170] mm); two inner black side-stripes extend to between the ears; buffy-brown pelage between all black side-stripes. The alarm calls of this species and *F. lemniscatus* are distinctive.

Paraxerus alexandri and *P. boehmi*. Considerably smaller (mean HB 120 mm for *P. alexandri*, 102 mm for *P. boehmi*); tawny-orange or brown mid-dorsal stripe from shoulders to rump, bordered on each side by a black side-stripe and a yellow/cream side-stripe.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Gabon sub-region]). Recorded from Cameroon (S of Sanaga R.), Equatorial Guinea (Rio Muni), Gabon, Congo, SW Central African Republic, extreme SW DR Congo, and Angola (Cabinda).

Funisciurus lemniscatus

Habitat Lowland evergreen humid rainforests; rare in secondary or disturbed vegetation (where *F. isabella* is the common species).

Abundance Common in favourable habitats.

Adaptations Diurnal and scansorial. The feet are long and narrow, well suited for terrestrial travel. Ribboned Rope Squirrels forage chiefly on the ground (47% of 167 sightings) and in low vegetation below 5 m; they are rarely seen above 5 m (4% of sightings; Emmons 1975, 1980). They build round nests (mean diameter 21 cm) of single, large, dead leaves taken from the ground, and lined with a ball of fine plant fibres (about 11 cm diameter). Nests have 2–3 entrances. Five individuals followed by radio-tracking used 17 nests: 11 exposed in small treelets (mean height 3.8 m, range 2–10 m), three in hollows

of standing trees or lianas (mean height 1.9 m, range 1.5–2.2 m) and three in hollow logs that lay on the ground. Exposed leaf nests are placed in the top of saplings where branches divide, in the top of stumps, in free-hanging tangles of lianas, or against tree trunks where an epiphyte, liana or branch provides a support. If disturbed at night by noise or vibration while in an exposed nest, will jump out quickly and run to refuge in another nest nearby (Emmons 1975). Tree-cavity dens had small entrances just large enough to admit the squirrel, and were too small to hold normal-sized nests.

Radio-collared squirrels left their nests at dawn and returned in the late afternoon or at nightfall (mean return time 18:22h; range 16:16–18:49h, $n = 14$) and thus had a long mean daily activity period of 11.22 h (Emmons 1975, 1980).

Foraging and Food Omnivorous. Insects can be captured by extending the highly extensible tongue into confined spaces (as into a deep vial when in captivity) (L. Emmons unpubl.). In Gabon, feeds on fruits and seeds (59% of dry mass of stomach contents, $n = 15$) and arthropods (36%). Arthropods consumed are mainly termites (100% occurrence) and ants (60%). Sometimes large numbers of termites are consumed, contributing up to 100% of a stomach content, indicating opportunistic feeding behaviour (Emmons 1980).

Social and Reproductive Behaviour Ribboned Rope Squirrels were usually seen alone (59% of 222 sightings), but sometimes in pairs (21%), threes (11%) and fours (7%). They are commonly observed in pairs or small groups, which join in alarm calling or foraging together, with individuals spaced at least 1 m apart, but more often 5–20 m apart. A captive heterosexual pair did not share nest boxes, the dominant often attacking the subordinate and defending food and space. A ♂ and ♀, with overlapping home-ranges, that were followed by radio-tracking for eight days (Emmons 1975, 1980) stayed within the same 0.5 ha for two days, but spaced 15–40 m apart. Home-ranges (assessed by radio-tracking) were 0.94 ha (subadult ♀), 1.0 ha and 1.24 ha (two adult ♂♂) and 1.6 ha (one adult ♀). During activity, ♂♂ moved at a mean rate of 51 m/h ($n = 9$ days of activity), and ♀♀ at 43 m/h ($n = 20$ days of activity).

Ribboned Rope Squirrels call readily and often (details in Emmons 1978). The low intensity alarm call is a series of chucks given in groups of 1–8, but most often in triplets (36% of 61 groups). The high intensity call is a similar series of more prolonged and frequency-modulated chucks or chips, which are linked together in groups of 1–7, but usually in pairs (43% of 83 calls) or triplets (47%). The linked calls drop in frequency between successive calls, and are often preceded by single chucks. Low intensity alarm calling is associated with a downward tail-flick display like that described for *F. anerythrus*.

Reproduction and Population Structure Embryo number: 1.8 (1–3, $n = 4$; Emmons 1979a); 1.7 (1–2, $n = 10$; Dubost 1968).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Funisciurus leucogenys RED-CHEEKED ROPE SQUIRREL

Fr. Funisciure à oreilles noires; Ger. Orangenköpfiges Baumhörnchen

Funisciurus leucogenys (Waterhouse, 1842). Ann. Mag. Nat. Hist., ser. 1, 10: 202. Bioko I., Equatorial Guinea.

Taxonomy Originally described in the genus *Sciurus*. The species name, which means ‘white-cheeked’, is a misnomer; Waterhouse apparently intended the more appropriate name *erythrogeus* (‘red-cheeked’) (Rosevear 1969). Synonyms: *auriculatus*, *beatus*, *boydi*, *erythrogeus*, *oliviae*. Subspecies: none. Chromosome number: not known.

Description Medium-sized squirrel with grey-brown pelage, red cheeks and one side-stripe on each flank broken into spots. Pelage colour varies geographically (see below). Dorsal pelage soft-textured, dark grey-brown to brownish-black; yellow on shoulders. Single side-stripe on each flank, whitish-yellow, broken into spots. Ventral pelage white or pale orange-red. Head and cheeks bright

orange-red; black speckling on crown of head. Ears rounded, black on outer surface; dark postauricular patch often present. Thighs and forearms greyish. Hindfeet more strongly built than forefeet. Tail long (ca. 79% of HB), bushy, hairs long; black or brownish-black with white tips above, red below. Tail constantly erect and frequently carried curled over back. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 2 + 2 = 8.

Geographic Variation Rosevear (1969) described four variations as subspecies; here considered as colour variants related to altitude and climate. (1) Ventral pelage white and side-stripe indistinctly broken into stripes (Bioko I.; *leucogenys*). (2) Ventral

pelage tinged with orange, side-stripe broken into spots, crown of head red, with obvious black patches behind ears, underside of tail brilliant red (Ghana, Togo, Nigeria and W Cameroon; *olivae*). (3) Ventral pelage tinged with orange, crown blackish-red, black patches behind ears; greyish-white 'frosted' mantle on shoulders (Upper Cameroon, Mt Cameroon; *auriculatus*). (4) Similar to *auriculatus*, but darker with buffy-grey mantle on shoulders (higher altitudes on Mt Cameroon and highlands; *boydi*).

Similar Species

F. anerythrus. Pelage drab; pale side-stripe not broken into spots; ventral pelage greyish; no dark postauricular patch; more common in secondary habitats.

F. pyrrhopus. Pale side-stripe not broken into spots, thighs and forearms bright red; no dark postauricular patch.

Distribution Endemic to Africa. Rainforest BZ (West Central Region, and extreme east of Western Region). Recorded from Ghana (east of Volta R.), Togo, Benin, Nigeria, Cameroon, Equatorial Guinea (Rio Muni) and Central African Republic (upper Sanga R.), Bioko I.

Habitat Lower strata in relatively undisturbed rainforest habitats and forest relics in rainforest–savanna mosaic (Sanderson 1940, Happold 1987). Of 19 individuals live-trapped in Dazing-Sangria, Central African Republic, eight were in unlogged mixed-species forest, eight in monodominant *Gilbertiodendron dewevrei* forest, two on skidder trails (i.e. trail used by a bulldozer to drag a log to the nearest road) and one on a secondary logging road (Ray 1996; J. C. Ray & J. R. Malcolm unpubl.).

Abundance No information.

Remarks Diurnal and arboreal (J. C. Ray & J. R. Malcolm unpubl.). During trapping at three heights in Dzanga-Sangha, Central African Republic, captured on ground and understorey (ca. 2 m), but not at 15 m (n = 9; Malcolm & Ray 2000; J. R. Malcolm unpubl.). Nests in holes entered either from tree hollow or from beneath vegetation or other suitable cover (Sanderson 1940). Vocalizations described as 'excited chattering with a staccato quality' (Rosevear 1969). Young born in simple nests lined with grass and leaves in holes among roots of trees. Pregnancies recorded in dry and early wet seasons (Dec, Feb and May) in Dzanga-Sangha. Embryo number: 1 (n = 3; J. C. Ray & J. R. Malcolm unpubl.).

Conservation IUCN Category: Data Deficient.

Deforestation and degradation of forests by logging and clearing constitute potential threats.

Funisciurus pyrrhopus FIRE-FOOTED ROPE SQUIRREL (RED-LEGGED ROPE SQUIRREL)

Fr. Funisciure à pattes rousses; Ger. Rotfüssiges Baumhörnchen

Funisciurus pyrrhopus (F. Cuvier, 1842). In: E. Geoffroy Saint-Hilaire and F. Cuvier, Histoire Naturelle des Mammifères, vii, No. 66. Tab. 4: 240. Gabon.

Taxonomy Originally described in the genus *Sciurus*. The type locality was described as 'et elle venoit de l'île Fernandopô, dans le gulfes de Guinée'. However, the species is not known from Fernando Poo (now Bioko I.) and since the animal was a pet, it probably came from the mainland (see Hoffman *et al.* 1993). Type locality is likely to be Gabon or Equatorial Africa (Rio Muni). Rosevear (1969)

refers to the species as *Funisciurus pyrrhopus* (with an 'h'), which is an unjustified emendation (Hoffmann *et al.* 1993). Taxonomy is reviewed in Amtmann (1966) and Rosevear (1969). Rosevear lists five subspecies, but does not include any forms east of the Sanaga R. in Cameroon, and Amtmann (1966) recognizes the nine subspecies given below. Some of the named forms (*leonis*, *mandingo*) were placed

in *F. anerythrus* by Rosevear (1969). The allocation and validity of named forms of *Funisciurus* squirrels is in need of revision. Synonyms: *akka*, *emini*, *erythropros*, *leonis*, *leucostigma*, *mandingo*, *nigrensis*, *niveatus*, *pembertoni*, *rubripes*, *talboti*, *victoriae*, *wintoni*. Subspecies: nine. Chromosome number: not known.

Description Beautiful, medium-sized, long-nosed squirrel with a dark back, pale side-stripe on each flank, and bright reddish limbs. Dorsal pelage grizzled greyish or blackish; hairs banded black with buff tip. Head below crown, muzzle, forelimbs below shoulders, and hindlimbs below hips brilliant rufous to dull rusty-red; hairs pure rufous or rusty-red. White or pale grey side-stripes. Ventral pelage pure white or off-white. Eyes ringed with buff. Ears pale behind. Tail long (ca. 80% of HB) and bushy; hairs banded, black at base, rufous distally, with white-frosted tip. When squirrel is at rest, tail is curled up over back; when moving, tail is carried with base vertical and tip curled backwards or horizontally straight behind body. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: $0 + 0 + 1 + 1 = 4$.

Geographic Variation Highly variable, as attested by the large number of named forms (see also above). Amtmann (1966) recognizes nine subspecies:

- F. p. akka*: E Congo, Uganda. Sides and crown without red; limbs and muzzle dull red; underparts washed orange.
- F. p. leucostigma*: S. Ghana. Red parts of pelage duller and brownish-red; sides below side-stripes red; crown not red.
- F. p. leonis*: Liberia and Sierra Leone. Red parts of pelage deep rufous; sides red.
- F. p. mandingo*: Gambia. Dorsal pelage pale, straw-coloured sprinkled with black; limbs and ears orange.
- F. p. nigrensis*: Nigeria from Cross R. to Niger R. Head brownish.
- F. p. niveatus*: Côte d'Ivoire. Red parts orange-red rather than rusty.
- F. p. pembertoni*: N Angola. Greyish, with limbs red.
- F. p. pyrropus*: S Cameroon to Mayumbe forest, Congo. Brightly coloured.
- F. p. talboti*: Mt Cameroon and SE Nigeria. Red on flanks mixed with greenish-brown.

Similar Species

- F. anerythrus*. Smaller (HB: 167–198 mm); pelage brown without red or rufous on limbs; whooping birdlike alarm call.
- F. leucogenys*. Limbs greyish similar in colour to back; black postauricular patch.

Distribution Endemic to Africa. Widespread but disjunct in Rainforest BZ (Western, West Central and East Central Regions), and Rainforest–Savanna Mosaics. Recorded from NW Angola, Burundi, Cameroon, Congo, Côte d'Ivoire, Equatorial Guinea (Rio Muni), Gabon, Gambia, SW Ghana, W Guinea, Guinea-Bissau, Liberia, SE Nigeria, Rwanda, S Senegal, Sierra Leone, Uganda and DR Congo. Although sympatric with *F. anerythrus* in the east of its range (Nigeria eastwards), it is allopatric in the west of its range (from Ghana westwards (Grubb *et al.* 1998).

Habitat Tall evergreen forest and older secondary forests.

Funisciurus pyrropus

Abundance Common in suitable habitat.

Adaptations Diurnal and terrestrial. Fire-footed Rope Squirrels have long, narrow feet, suitable for terrestrial living. They forage on the ground and on fallen logs and brush below 1.5 m. Unlike other squirrels, they build nests on the ground and in burrows. Of 17 nest sites used by four individuals (found by radio-tracking), 14 were in underground burrows and three in hollow logs on the ground. Six burrows were of characteristic structure and were probably dug by the Fire-footed Rope Squirrels themselves. These were simple tubes, often constructed within a termite nest, with an entrance at each end and a central nest chamber (illustrated in Emmons 1975). The other burrows were probably excavated by other mammals, such as *Cricetomys emini* (1 den) and *Atherurus africanus* (1 den), and were likely to be used opportunistically by these squirrels. Radio-tracked individuals left their nest soon after daylight and returned to it at 15:18–18:52h ($n = 17$ times of return; Emmons 1980), and hence had a mean daily activity period of 9.86 h.

Foraging and Food Omnivorous. The long muzzle is probably associated with hunting insects in small crevices. In Gabon, feeds on fruit and seeds (83% of dry matter of stomach contents, $n = 12$) and insects (12%) (Emmons 1980). The insect portion of the diet consists chiefly of ants (100% occurrence) and termites (92% occurrence). These are consumed in large numbers – soldiers, workers, eggs and larvae together – suggesting that the squirrels find and raid ant and termite nests.

Social and Reproductive Behaviour Fire-footed Rope Squirrels appear to be mainly solitary: 80% of individuals ($n = 56$ sightings) were of single individuals, and 14% were in groups of two that were widely spaced and engaged in mobbing. In captivity, a heterosexual pair slept in different nest boxes and did not groom each other until they had been together many months. A 'mating chase',

when several ♂♂ pursued a ♀, has been observed (Emmons 1980). Home-ranges (assessed by radio-tracking) were 5.2 ha (one adult ♂), 1.0 ha (a lactating ♀) and 2.3 ha (a subadult ♀). Movements were slow, at a mean rate of 35 m/h for two ♀♀ and 61 m/h for two ♂♂ (Emmons 1975).

Vocalizations are frequent (Emmons 1978). The low intensity alarm is a loud single chuck, or more rarely, a double chuck. The high intensity alarm is distinctive and consists of a staccato, machine gun-like series of chucks, lasting about 20–40 seconds (tatatatatatatatata . . .). This call superficially resembles that of *Epixerus ebii*, and is unlike the calls of any sympatric *Funisciurus* species. The tail-flick display during low intensity alarm is similar to that described for *F. anerythrus*.

Reproduction and Population Structure Litter-size usually seems to be one (range 1–2), but there are few records (Emmons 1979a).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Funisciurus substriatus KINTAMPO ROPE SQUIRREL

Fr. Funisciure de Kintampo; Ger. Kintampo-Baumhörnchen (Togo Streifenhörnchen)

Funisciurus substriatus de Winton, 1899. Ann. Mag. Nat. Hist., ser. 7, 4: 357.

‘near Kintampo, Gold Coast hinterland, 800 feet (240 m)’ (= Kintampo, Ghana).

Taxonomy This form is usually listed as a valid species (Amtmann 1975; Hoffmann *et al.* 1993), but there is underlying doubt about species limits in *Funisciurus*. This species closely resembles *Funisciurus anerythrus*, a species originally described from W Uganda. It is not clear whether *Funisciurus substriatus*, distributed from E Ghana to Benin, is reproductively isolated from populations further east and south and which are here described as *Funisciurus anerythrus*. Synonyms: none. Chromosome number: not known.

Description Medium-sized plain-coloured squirrel with single faint pale stripe on each flank, very similar to *F. anerythrus*. Dorsal pelage greenish-yellow or ochre, heavily speckled with black; especially pale in Burkina. Single side-stripe on each flank, faint, whitish, bordered ventrally by darker stripe. Ventral pelage white, occasionally suffused with pale ochre; hairs dark grey at base. Fore- and hindlimbs similar to dorsal pelage. Tail long (ca. 100% of HB), similar but darker than back, with noticeable rings of black and buff; dorsal hairs black with short pale tips; lateral hairs with long pale buff tips, ventral hairs ochre. Skull: cheekteeth ⁵/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 0 + 0 + 1 + 1 = 4.

Geographic Variation None recorded.

Similar Species

F. anerythrus. Very similar in form and colour; distinguished mainly by distribution; ventral pelage does not show the ochre to orange colouration of populations of *Funisciurus anerythrus* to the east and south of Cameroon.

Funisciurus substriatus

Distribution Endemic to Africa. Guinea Savanna BZ and Northern Rainforest-Savanna Mosaic and some relict forests in Sudan Savanna BZ. Recorded from Burkina, E Ghana, Togo and Benin. Does not appear to extend eastwards into Nigeria (where replaced by *F. anerythrus*), or westwards to Côte d'Ivoire.

Habitat Woodland savanna and remnant forests; rocky habitats and along rivers in Burkina (specimen labels).

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

GENUS *Heliosciurus*

Sun Squirrels

Heliosciurus Trouessart, 1880. Le Naturaliste, 2nd year, 1: 292. Type species: *Sciurus gambianus* Ogilby, 1835.

Heliosciurus rufobrachium.

Heliosciurus comprises six species of small to large tree squirrels widely distributed in sub-Saharan Africa except for arid or treeless regions. There are representatives in rainforest and montane forest (three spp.) and in savanna habitats (three spp.). Two species are widespread while four have rather small ranges. The vernacular name 'Sun Squirrel' is a literal translation of the generic name, and refers to the habit of these squirrels of living at higher levels in the forest where they are more likely to encounter sunny habitats.

The genus is characterized by moderate size (HB: 170–270 mm, larger than *Myosciurus* and *Funisciurus*, but smaller than *Protoxerus* and *Epixerus*), slender build, and long tail, usually longer in length than HB. The pelage of the back and flanks is speckled and there is no lateral side-stripe (cf. *Funisciurus*). The head is relatively large, with small ears held close to the skull. The limbs are relatively long. The colouration of *Heliosciurus* squirrels is typically greyish or brownish, but one species has rufous or reddish limbs and shoulders (*H. rufobrachium*) and another has reddish-brown or rufous-brown body pelage (*H. mutabilis*). The tail is covered with long hairs, each alternately banded with dark and pale bands; the tail is extended

Figure 12. Skull and mandible of *Heliosciurus gambianus* (BMNH 62.346).

backwards in line with the body when the squirrel is running along branches, and hangs downwards when the squirrel is resting (cf. *Funisciurus*). Females have three pairs of nipples (not four as in *Allosciurus*, *Protoxerus* and *Epixerus*). Baculum absent.

The length of the skull is larger than that of *Myosciurus*, overlaps extensively with that of *Allosciurus*, *Paraxerus* and *Funisciurus*, but is smaller than in *Protoxerus* and *Epixerus*. The skull is characterized by orange ungrooved incisors (except *H. rufobrachium* – slightly grooved), fossa for the origin of anterior deep masseter muscle extending onto the rostrum, supraorbital notch which is closed on margin of orbit forming a foramen piercing the frontal bone, large sphenopalatine foramina, anterodorsal process of premaxilla, which

Table 12. Species in the genus *Heliosciurus*. Arranged according to amount of red colouration on the pelage.

| Species | Red colouration on pelage | Colour of ventral pelage | HB mean (range) (mm) | HF mean (range) (mm) | GLS mean (range) (mm) | Number of cheekteeth (upper/ lower) | Notes |
|------------------------|---|---|----------------------|----------------------|-----------------------|-------------------------------------|---|
| <i>H. gambianus</i> | None | White, cream or buff; sparse | 196 (180–230) | 44 (40–50) | 37 (45–51) | ⁴ / ₄ | Widespread savannas N and S of Rainforest BZ |
| <i>H. undulatus</i> | None | Whitish-grey to ochre | 233 | 56 | 32 | ⁴ / ₄ | Lowland and montane forests SE Kenya, NE Tanzania, Mafia and Zanzibar Is. |
| <i>H. punctatus</i> | None | Grey | ca. 390 (355–524) | 46 (37–50) | 47 (37–50) | ⁴ / ₄ | Rainforest and forest relicts, Liberia to Ghana |
| <i>H. ruwenzorii</i> | None | Creamy-buff, with white mid-ventral stripe | 240–260 | 54 | 51–52 | ⁵ / ₄ | Montane forests E DR Congo, Rwanda, Uganda, NW Burundi |
| <i>H. mutabilis</i> | Rufous cinnamon (new pelage) | Creamy-buff; sparse | 236 (217–269) | 53 (46–60) | 54 (52–56) | ⁴ / ₄ | Savannas of eastern Africa; eastern part of Zambesian Woodland BZ |
| <i>H. rufobrachium</i> | Shoulders and limbs rufous to reddish (very varied) | Brown, reddish, rufous, grizzled as dorsal pelage | ca. 230 (205–249) | 47–49 (40–56) | 53 (50–54) | ⁴ / ₄ | Widespread throughout Rainforest BZ and forest relicts |

risers to about level with anterolateral angle of nasal, prominent masseteric tubercle (unlike all other African tree squirrels), and the posterior end of bony palate is approximately in line with the posterior end of M³ (Figure 12). There are four cheekteeth in each ramus (⁴/₄), although *Heliosciurus ruwenzorii* (⁵/₄) has a very small additional tooth (P³). Dental formula: I ¹/₁, C ⁰/₀, P ¹/₁, M ³/₃ = 20 (except *H. ruwenzorii* – see above; cf. *Paraxerus*).

Two species are widespread (*H. gambianus*, *H. rufobrachium*) and four species have rather constricted ranges. All are arboreal. *Heliosciurus ruwenzorii* lives in montane forest, *H. rufobrachium* and *H. punctatus* in lowland rainforest, *H. undulatus* and *H. mutabilis* in forests and woodlands of East Africa, and *H. gambianus* lives primarily in savannas of West Africa. The species are mostly allopatric, but *H. punctatus* is entirely sympatric with *H. rufobrachium*, and the range of *H. gambianus* is parapatric with that of *H. rufobrachium* at least in West Africa, though the two species are ecologically segregated. These squirrels are mostly seen singly or in pairs. Sun Squirrels produce a large variety of vocal noises, which are mostly species-specific.

Heliosciurus forms a monophyletic clade with *Allosciurus*, *Protoxerus* and *Epixerus* (Moore 1959). There has been some disagreement concerning the allocation of subspecies to species. The taxa *brauni*, *coenosus*, *emissus* and *lualabae*, including the populations in the rainforest south of the Congo R., were allocated to *H. gambianus* by Amtmann (1975) but to *H. rufobrachium* by Thorington & Hoffmann (2005). *Heliosciurus ruwenzorii* was formerly placed in subgenus *Aethosciurus* (Ellerman 1940), whose type species (*poensis*) is now included in *Paraxerus*. The genus is placed in the subfamily Xerinae and tribe Protoxerini (which also includes all the other African sciurids except for *Atlantoxerus* and *Xerus* – the Ground Squirrels – which are placed in the tribe Xerini) (Thorington & Hoffmann 2005).

Species in the genus are distinguished by presence/absence of reddish colouration of the pelage, colour of ventral pelage, bushiness of the tail, body and skull size, and habitat (Table 12).

Peter Grubb

Heliosciurus gambianus GAMBIAN SUN SQUIRREL

Fr: Heliosciure de Gambie; Ger. Gambisches Sonnenhörnchen

Heliosciurus gambianus (Ogilby, 1835). *Proc. Zool. Soc. Lond.* 1835: 103. ‘brought from Gambia’, possibly near Fort St Mary, Gambia.

Taxonomy Originally described in the genus *Sciurus*. Geographic variation in pelage colour over an extensive range has led to the description of 20 forms of *H. gambianus* (Hoffman *et al.* 1993), many of which are synonyms. The rainforest representative, *H. punctatus*, originally regarded as a subspecies (e.g. Rosevear 1969), is now considered to be a separate species (Roth & Thorington 1982). Synonyms: *abassensis*, *albina*, *annularis*, *annulatus*, *bongensis*, *canaster*, *dysoni*, *elegans*, *hoogstraali*, *kaffensis*, *lateralis*, *limbatus*, *loandicus*, *madogae*, *multicolor*, *omensis*, *rhodesiae*, *senescens*, *simplex*. Subspecies: none. Chromosome number: not known.

Description Medium-sized arboreal greyish-brown squirrel with long banded tail, and mostly without any obvious bright colours or markings; considerable geographic variation in colour (see below). Pelage short, slightly coarse. [Description of form *gambianus*] Dorsal pelage and flanks grizzled pale brown or buff, flecked with black; dorsal hairs with alternating black and buff bands, usually with black tip. Ventral pelage sparse (so skin visible in parts), hairs longer than on dorsal pelage, pure white, cream or buff. Forehead and muzzle similar to dorsal pelage. Chin, throat, chest, as ventral pelage. Eyes large, dark. Ears small and rounded, covered with short hairs,

Heliosciurus gambianus.

situated close to head. Fore- and hindlimbs short, grizzled buff without any rufous colour (cf. *H. rufobrachium*). Forefeet with four digits (D1 vestigial), each with long claw; hindfeet with five digits, each with long claw. Tail long (ca. 110% of HB), buff with up to 15 black circular bands, some clearly defined, others obscure; hairs buff with 3–4 alternating black bands. Skull: cheekteeth $4/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle prominent. Nipples: $0 + 1 + 1 + 1 = 6$.

Geographic Variation Considerable geographic variation in pelage colour, although these differences in colour are not recognized as subspecific. For example:

H. g. gambianus: West Africa. See Description above.

H. g. dysoni: Ethiopia, S Sudan. Dark brown with bright rufous around genitalia, around base of tail and on undersurface of tail.

H. g. elegans: Uganda. Medium brown; hairs with wide whitish-cream bands provide a flecked pattern on pelage (rather than a grizzled pattern).

H. g. rhodesiae: Zambia. Greyish-cream; hairs longer and softer than in other forms. A larger and heavier form than those in East and West Africa.

Similar Species

H. rufobrachium. Larger (HB: 212–249 mm); limbs red; rainforest habitats; mostly allopatric.

H. mutabilis. Larger (HB: 217–269 mm); limbs brownish; savanna habitats; allopatric.

H. punctatus. Similar in size (HB: ca. 180–190 mm); pelage dark; rainforest and mosaic habitats; restricted to Rainforest BZ (Western Region).

Distribution Endemic to Africa. Guinea and Sahel Savanna BZs, Northern Rainforest–Savanna Mosaic, Southern Rainforest–Savanna Mosaic, and Zambezian Woodland BZ. Recorded from Senegal and Gambia eastwards across West and central Africa to S Sudan, Eritrea and Ethiopia; and from Angola, S DR Congo, N Zambia (west of the Muchinga escarpment) and extreme SW Tanzania (Ufipa Mts). Outlier populations (which appear to be isolated from the main geographic range) on Jebel Marra (W–C Sudan) and C Tanzania (Tabora).

Heliosciurus gambianus

Habitat Wooded savanna, especially where savanna trees are denser and taller than average because of better soil and access to water (Rosevear 1969). Preferred habitats include Guinea savanna of West Africa (Rosevear 1969), savanna woodlands and secondary forest in Uganda (Delany 1975), and *Brachystegia* woodland in Zambia (Ansell 1960). Also recorded from rather dry locations in E Uganda (e.g. Karamoja) and NW Kenya (e.g. Lodwar, west of L. Turkana). Along the margins of the Rainforest BZ, Gambian Sun Squirrels have moved into areas where forests have been replaced by palm plantations and other savanna-like habitats (Happold 1987). Here they may occur sympatrically with *H. rufobrachium* and *Paraxerus* spp. (Rosevear 1969).

Abundance Widely distributed and not uncommon in suitable habitats. Probably the most frequently seen of the tree-living savanna squirrels. In many localities, it is the only species of arboreal squirrel. Quantitative information on abundance not available.

Adaptations Arboreal and diurnal. Gambian Sun Squirrels are very agile, running along branches, and jumping from one tree to another where the canopies are close together. In more open woodlands, they descend to the ground to forage and to travel (usually with a short bounding gait) to adjacent trees. They are active only during the day, especially the early morning and late afternoon, and they rest at night in nests, lined with leaves, in holes of trees. Gambian Sun Squirrels are remarkably tolerant of a wide range of environmental conditions, from well-wooded moist savannas to dry semi-arid savannas. There is no detailed ecological and behavioural information on this widespread and common species.

Foraging and Food Mainly vegetarian, but also omnivorous. The diet includes fruits, nuts and insects, and occasionally eggs, geckos, lizards and nestlings are consumed (Ansell 1960, Delany 1975).

Social and Reproductive Behaviour Usually observed as single individuals, suggesting they are solitary. Vocalizations are important for communication and include high-pitched squeaks, various chattering and trilling notes, and a long ‘ker ... ker ... ker’ emitted when alarmed (Delany 1975).

Reproduction and Population Structure Embryo number: 5 ($n = 1$), 1 ($n = 1$) in Zambia (Ansell 1960). Young (about one-third grown) observed in Zambia in Sep and Oct. Young individuals in Karamoja (Uganda) in Feb (Kingdon 1974). Young born in nests in holes in trees; at birth young are almost naked and the eyes are closed.

Predators, Parasites and Diseases No detailed information, but likely to be preyed upon by diurnal birds of prey.

Conservation IUCN Category: Least Concern.

Unlikely to be threatened: a relatively common species with a very large geographic range.

Measurements

Heliosciurus gambianus gambianus

HB: 196.6 (180–230) mm, $n = 10$

Heliosciurus mutabilis MUTABLE SUN SQUIRREL

Fr. Heliosciure variable; Ger. Mutaibles Sonnenhörnchen

Heliosciurus mutabilis (Peters, 1852). Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 17: 273. ‘Africa orientalis, Boror, 17° Lat. Austr.’ (= Boror, 19 km NW of Quelimane, Mozambique).

Taxonomy Originally described in the genus *Sciurus*. The form *mutabilis*, originally described as a valid species, is considered either as a subspecies of *H. gambianus* (e.g. by Ellerman [1940] and Swynnerton & Hayman [1950]) or of *H. rufobrachium* (e.g. by Rosevear [1963], Smithers & Lobão Tello [1976], Ansell [1978], Smithers & Wilson [1979], and De Graaff [1981]). Grubb (1982) showed that *mutabilis* is a valid species clearly separable from *H. gambianus* and *H. rufobrachium*, a systematic opinion followed by Ansell & Dowsett (1988), Hoffman *et al.* (1993) and in this volume. Grubb (1982) lists five subspecies; Hoffman *et al.* (1993) and Thorington & Hoffman (2005) list these forms as ‘synonyms’ without distinction between synonyms and subspecies (see below). Synonyms: *beirae*, *chirindensis*, *shirensis*, *smithersi*, *vumbae*. Subspecies: five (but see below). Chromosome number: not known.

Description Large brown or rufous-brown squirrel, often with patches of contrasting colour on different parts of the body, which result in a scruffy unkempt appearance. Pelage long (15–20 mm on mid-back), slightly coarse. Dorsal pelage and flanks brown or rufous-brown, abundantly flecked with cream. Dorsal hairs with five bands: brown at base, two paler bands and a broad buff band in centre, and cream at tip. Ventral pelage sparse; hairs long, cream or buff. No side-stripe. Head, cheeks and limbs similar to dorsal pelage. Fore- and hindlimbs (outer and inner surfaces) grey or brown (not russet or red as in *H. rufobrachium*). Tail long (ca. 112% of HB), dark blackish-brown with up to ten obscure cream or buff bands. Tip of tail may be rufous or rich cinnamon (especially when pelage is old). Striking colour changes occur when moulting: newly moulted pelage is cinnamon, rufous or chestnut, and brightly coloured; as the pelage ages, it becomes brown or blackish-brown, and dull. In many

individuals moulting occurs in patches, so the dorsal pelage appears as a patchwork of brown, black, cinnamon and rufous, partly bright, partly dull – a pattern quite unlike that seen in any other species of squirrel. Hence pelage shows seasonal changes in colour and pattern, as well as geographical variation. Skull: cheekteeth $4/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle prominent. Nipples: $0 + 1 + 1 + 1 = 6$.

Geographic Variation Mutable Sun Squirrels show considerable variation in pelage colouration within populations (mainly due to moulting patterns – see above) and between populations. In Malawi, for example, the following variation is visible in a series of specimens: (a) crown of head and upper back black, mid-back and flanks bright cinnamon, tail rufous with paler bands; (b) dorsal pelage cinnamon, flecked with buff; (c) crown of head, dorsal pelage and tail dark rufous or chestnut brown, flanks cinnamon flecked with pale buff, tail without any discernible bands. In other parts of the range (e.g. E Zimbabwe) some individuals are almost black. The pelage of populations living in montane habitats is particularly long and intensely pigmented, and without cream flecking (P. Grubb unpubl.).

Grubb (1982) recognized five subspecies but suggested that much of the colour variation is clinal. Because variation within populations may obscure geographic variation, only the distribution of each of these taxa is provided:

H. m. shirensis: S and E Zambia, N Malawi, SW Tanzania. The most widespread form.

H. m. beirae: S Tanzania and coastal Mozambique.

H. m. chirindensis: highland regions of E Zimbabwe and adjacent Mozambique.

H. m. mutabilis: S Malawi and adjacent Mozambique.

H. m. vumbae: SE Zimbabwe and adjacent Mozambique.

Similar Species

Paraxerus cepapi. Smaller (HB: 145–203 mm); dorsal pelage dull grey or yellowish-brown; no side-stripe; cheekteeth $4/4$.

Paraxerus palliatus. Similar size (HB: 187–221 mm); brightly coloured with rufous or red on ventral ventrum, cheeks and/or tail; no side-stripe; cheekteeth $4/4$.

Paraxerus flavovittis. Smaller (HB: 165–176 mm); dorsal pelage rusty-brown or red-brown; white side-stripe bordered by lower black stripe; cheekteeth $4/4$.

Distribution Endemic to Africa. Eastern parts of Zambezan Woodland BZ and southern parts of Coastal Forest Mosaic BZ, including some highland regions. Recorded from S Tanzania, E Zambia, Malawi, E Zimbabwe, and S and C Mozambique. May occur in N Mozambique, but no definite records. Recorded from sea level to ca. 2100 m. In Tanzania, replaced by *H. undulatus* north of Rufigi R.

Habitat Very varied: montane forests, *Brachystegia* woodland savanna, especially where trees are dense, thickets, riparian forests and coastal forests. Sometimes occurs in mopane woodlands (Dowsett 1969).

Abundance Uncertain; may be quite common in suitable habitats.

Adaptations Arboreal and diurnal. Runs quickly and nimbly among denser branches and twigs, and in the canopy of trees. Nests in holes of trees.

Foraging and Food Mostly vegetarian. Feeds on wild fruits, berries, nuts, fresh green shoots and flowers; occasionally eats insects and eggs (Smithers 1966, Smithers & Wilson 1979).

Social and Reproductive Behaviour Normally observed as solitary individuals or in pairs. When alarmed, makes loud ‘clucking’ sounds and flicks tail, and sometimes lies flat along the length of a branch or hides in a tree hole (Smithers 1966, 1986a).

Reproduction and Population Structure Young born in ‘summer months’ in Zimbabwe. Litter-size: up to four (Smithers 1986a).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Heliosciurus punctatus PUNCTATE SUN SQUIRREL (SMALL SUN SQUIRREL)

Fr. Heliosciure de forêt; Ger. Geflecktes Sonnenhörnchen (Kleine Sonnenhörnchen)

Heliosciurus punctatus (Temminck, 1853). Esquisses Zoologiques sur la Côte de Guinée, p. 138. ‘dans toutes les forêts de la Guinée’. Guinea coast, no exact locality given. Ingoldby (1927) suggested type locality as ‘Secondi and Bibiani, Gold Coast’, Ghana.

Taxonomy Originally described in the genus *Sciurus*. Considered as a subspecies of *H. gambianus* by Ingoldby (1927), Ellerman (1940), Rosevear (1969) and Amtmann (1975), but as a valid species by Allen (1939), Roth & Thorington (1982), Hoffman *et al.* (1993) and Grubb *et al.* (1998). Rosevear (1969) commented that *punctatus* was ‘obviously merely a form of *gambianus* darkened through residence

in the moister climate of the forest’. Included in *H. gambianus* by Kingdon (1997). Synonyms: *savannius*. Subspecies: two. Chromosome number: not known.

Description Medium-sized rather dark squirrel, with long ringed tail. Pelage long and soft. Dorsal pelage and flanks dark brown

grizzled with buff; hairs sepia at base, bands of dark and buff distally, with black tip. Ventral pelage greyish. Insides of thighs dark grey. Tail long (ca. 120% of HB), slender, banded with dark and pale rings; hairs dark with white tip; underside paler than the upperside. Skull: cheekteeth $4/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle prominent; comparatively larger braincase than in *H. gambianus*. Nipples: $0 + 1 + 1 + 1 = 6$.

Geographic Variation

H. p. punctatus: forest regions from Liberia to Volta R., Ghana. Darker coastal form.

H. p. savannius: savanna regions of Côte d'Ivoire. Paler inland form.

Similar Species

H. gambianus. Similar but with paler ventral pelage; smaller braincase; different distribution.

H. rufobrachium. Larger; reddish colouration on limbs.

Distribution Endemic to Africa. Rainforest BZ (Western Region) and Northern Rainforest–Savanna Mosaic. Recorded from Sierra Leone, E Liberia, S Côte d'Ivoire and S Ghana (west of the Volta R.).

Habitat Primary and secondary rainforest (including open areas), relict forests in Rainforest–Savanna Mosaic, and southern parts of the Guinea Savanna BZ.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Heliosciurus rufobrachium RED-LEGGED SUN SQUIRREL

Fr. Héliosciure à pieds roux; Ger. Rotbeiniges Sonnenhörnchen

Heliosciurus rufobrachium (Waterhouse, 1842). Ann. Mag. Nat. Hist., ser. 1, 10: 202. Fernando Poo (= Bioko I., Equatorial Guinea).

Taxonomy Originally described in the genus *Sciurus*. Rosevear (1969) and Amtmann (1966) recognized two species from the *gambianus*-like group of Sun Squirrels: *H. gambianus* for small, pale-coloured squirrels from dry habitats, and *H. rufobrachium* for large, darker squirrels from wetter habitats. Subsequently Grubb (1982) allocated specimens of this species from S Tanzania, Malawi, Mozambique, Zambia and Zimbabwe to *H. mutabilis* (see species profile). Hoffman *et al.* (1993) list 26 synonyms, attesting to the large amount of variation within the species (see below, and Thorington & Hoffman 2005). Synonyms: *acticola*, *arthenii*, *aschantiensis*, *aubryi*, *benga*, *brauni*, *caurinus*, *coenosus*, *emissus*, *hardyi*, *isabellinus*, *keniae*, *leakyi*, *leonensis*, *libericus*, *lualabae*, *maculatus*, *medjanius*, *nyansae*, *obfuscatus*, *occidentalis*, *pasha*, *rubricatus*, *rufobrachius*, *semlikii*, *waterhousii*.

Subspecies: possibly 16. Chromosome number: not known.

Description Large dark brown to grey squirrel with red-tinged limbs and a slender faintly banded tail with pale yellow and blackish bands. Dorsal pelage dark brown, grey or rusty-red, grizzled with buff; hairs have 3–5 bands of dark brown and buff. Variation in the colour of bands produces the many local variations in overall pelage colour. Ventral pelage pale brown, whitish-brown, reddish or orange, grizzled as in dorsal pelage. Shoulders, limbs, inner surface of hindlimbs vary from bright rusty-red to grizzled brown or grey. Head smallish, slightly flattened. Ears short. Eyes large, often bordered by a pale eye-ring. Tail long (ca. 195% of HB), slender, faintly banded with paler bands; carried straight out behind or drooping downward

over a branch, not curled up against back. Skull: cheekteeth $4/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle prominent. Nipples: $1 + 0 + 1 + 1 = 6$.

Geographic Variation There is much geographical variation in colour, especially in the overall colour of the pelage, and in the colour and intensity of colour of the limbs. Of the 32 named forms, Amtmann (1966) synonymized several forms and listed 16 subspecies (four of them now included in *H. mutabilis*) without detail.

H. r. arrhenii: N Kivu, DR Congo.

H. r. aubryi: SW Central African Republic, Gabon, DR Congo between Tshuapa and Kasai rivers.

H. r. caurinus: Guinea-Bissau.

H. r. hardyi: Côte d'Ivoire.

H. r. isabellinus: E Nigeria to Togo.

H. r. keniae: western slope of Mt Kenya.

H. r. leonensis: Sierra Leone.

H. r. maculatus: Liberia.

H. r. medjanius: DR Congo.

H. r. nyansae: Nyando R. valley, Kenya, Tanzania west of L. Victoria.

H. r. obfuscatus: SE Nigeria, Mt Cameroon.

H. r. pasha: DR Congo.

H. r. rufobrachium: Bioko I.

H. r. semlikii: Semliki R., DR Congo.

Similar Species

H. mutabilis. Paler, less rufous on limbs; multi-coloured pelage during moult; allopatric to *H. rufobrachium*.

H. gambianus. Paler without any reddish colouration; mainly savanna habitats.

H. ruwenzorii. Broad, mid-ventral white stripe; restricted distribution only near Albertine Rift Valley.

Protoxerus stangeri. Much larger, with grizzled grey head, conspicuously bushy tail and sharply delineated almost naked yellow belly.

Distribution Endemic to Africa. Widespread in Rainforest BZ (Western, West Central and East Central Regions), Northern and Eastern Rainforest–Savanna Mosaics, and parts of Guinea Savanna BZ. Recorded from Benin, Burundi, Cameroon, Central African Republic, Congo, Côte d'Ivoire, Equatorial Guinea, Gambia, Ghana, Guinea, Guinea-Bissau, W Kenya, Liberia, Nigeria, Rwanda, Senegal, Sierra Leone, N Tanzania, Togo, Uganda, DR Congo, Bioko I.

Habitat Habitats with large trees in lowland evergreen moist rainforests, secondary forests, plantations and gardens in Rainforest BZ; forest outliers and some relict forests in savanna.

Abundance Common.

Adaptations Diurnal and arboreal. Red-legged Sun Squirrels live in the canopy and middle levels of the forest. They are morphologically adapted for arboreal life, with a long back, short limbs and short broad feet. Red-legged Sun Squirrels nest within tree hollows and prefer those with small entrances. Fifteen nest holes in Gabon were at a mean height of 8.8 m (range 1–20 m). Nests within the tree hollows are constructed of sprays of green leaves attached to their

Heliosciurus rufobrachium

twigs (Emmons 1975). In Gabon, Red-legged Sun Squirrels left their nests at dawn, but often returned well before dark (mean hours of activity 9.46 h); mean time of nest entry 15:55h; range 12:21–18:31h; $n = 13$).

Foraging and Food Omnivorous. In Gabon, feed on fruits and seeds (89% by dry mass of stomach contents), green vegetative parts of plants (6%) and arthropods (5%) ($n = 15$ stomachs). Although the nutritional return is evidently low, Red-legged Sun Squirrels spend much of their time hunting for arthropods (76% of 38 observations, Emmons 1980) by searching intently along branches and lianas, poking their nose into crevices and cavities, and rummaging around in epiphytes and suspended debris. Red-legged Sun Squirrels have a predatory, mongoose-like appearance, and they sometimes move with a slow, sneaking, weasel-like gait. In captivity they quickly captured and ate birds flying within their cages, killing them with bites to the head; and they readily ate bird's eggs as well as arthropods (Emmons 1975). Arthropods identified in the diet included ants, lepidopteran larvae, Coleoptera and others.

Social and Reproductive Behaviour Red-legged Sun Squirrels in the wild have been observed singly (60% of observations), in pairs (32%) and in threes (5%) ($n = 128$ sightings). In captivity they were gregarious and contact-loving: two adult ♂♂ and a ♀ always crammed themselves tightly together to sleep in the same nest box, and they frequently groomed each other and rested in physical contact, often draped over one another. They had a strict dominance hierarchy with respect to food. Wild pairs of undetermined sex were seen to forage, groom each other, play and rest together. Two radio-collared ♂♂ and two ♀♀ nested and travelled alone (Emmons 1975, 1980). The social organization is thus unclear, but bonded pairs seem likely.

Squirrels of this species are not highly vocal and are heard calling more rarely than are other species of squirrel (Emmons 1978). The

low intensity alarm call is a single- or double-pulsed chuck or bark, given in groups of 1–3, most often singly. The squirrel may call repeatedly for a few minutes. The distinctive high intensity alarm call sounds somewhat like the cooing of a dove. It has two parts: a low amplitude, descending frequency whine immediately followed by a short, rapid trill of low frequency pulses. During a calling bout, usually only one, or at most a few, calls are emitted at long intervals. Alarm chucks are emitted with a visual display similar to that of *Paraxerus poensis*. As the call is emitted, the tail is jerked upward in a stiff C shape, or with a somewhat circular sweep, and the feet are stamped on the substrate. If the squirrel is sitting with the tail hanging below, the tail may be jerked stiffly in random directions.

Reproduction and Population Structure Litter-size: 1–2, with more litters of one than of two (Rahm 1970). Pregnancy rate seems low; none of 11 adult ♀♀ collected in all seasons in Gabon was pregnant (L. Emmons & G. Dubost unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Heliosciurus ruwenzorii RWENZORI SUN SQUIRREL

Fr. Héliosciure de Rwenzori; Ger. Ruwenzori Sonnenhörnchen

Heliosciurus ruwenzorii (Schwann, 1904). *Ann. Mag. Nat. Hist.*, ser. 7, 13: 71. Wimi Valley, Rwenzori, E DR Congo.

Taxonomy Originally described as *Sciurus rufobrachiatatus ruwenzorii*. Formerly included in the genus *Aethosciurus*, which is here included in *Paraxerus* following Moore (1959). Synonyms: *ituriensis*, *schoutedeni*, *vulcanius*. Subspecies: four. Chromosome number: not known.

Description Medium to large grey squirrel with broad white stripe running down the underside from the throat to the genitals; geographical variation in pelage colour (see below). Pelage thick and dense. Dorsal pelage and flanks medium grey, slightly grizzled. Ventral pelage (on either side of white stripe) creamy-buff to olivaceous. Hairs pure white in ventral stripe. Head and outer surface of limbs grey. Chin, throat and chest white. Tail long (ca. 110% of HB) and slender, markedly banded with alternating grey and white bands. Skull: cheekteeth $\frac{5}{4}$ (anterior premolar P³ small); posterior end of bony palate in line with posterior end of M³; masseteric tubercle prominent. Nipples: 0 + 1 + 1 + 1 = 6.

Geographic Variation

H. r. ituriensis: E DR Congo (mountains west of L. Albert near Djalasinda and Djugu). Darker ventrally, showing less contrast with the dorsal pelage than in *H. r. ruwenzorii*; tail blacker; dorsal surfaces of feet less brown.

H. r. ruwenzorii: W Uganda and E DR Congo (Rwenzori Mts, 1980–2590 m). See Description above.

H. r. schoutedeni: E DR Congo (mountains from west of L. Edward to west of L. Kivu, area around Kahuzi-Biega N. P.), NW Rwanda (Parc National des Volcans, as *vulcanius*), SW Uganda. Brown on feet and muzzle; ventral pelage beige on either side of the white stripe.

Heliosciurus ruwenzorii

H. r. vulcanius: NW of L. Tanganyika (Mt Kandashomwa, 2330 m, Itombwe area), NW Burundi (Kibira N. P.), SW Rwanda (Nyungwe N. P., usually above 2000 m). Dorsal pelage sooty-brown, finely speckled with pale buffy; ventral pelage washed with ochraceous on either side of white stripe; rufous on feet.

Similar Species

Heliosciurus spp. Third upper premolar absent; without white ventral stripe.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Montane forests of E DR Congo, W Rwanda, W and SW Uganda and NW Burundi.

Habitat Montane and bamboo forests (1600–2700 m) (*H. r. ruwenzorii*); montane forests, gallery forests and forest edges and lightly wooded areas (*H. r. schoutedeni*, *H. r. vulcanius*), transitional and disturbed montane forests (*H. r. ituriensis*), cultivations (*H. r. vulcanius*).

Abundance Uncertain. Formerly common in the forests of Rwenzori Mts.

Adaptations Diurnal and arboreal. Lives mainly in lower vegetation rather than in the canopy. One nest was made of grass and leaves (Rahm & Christiaensen 1963). When travelling, the tail is held horizontally, in line with the body (Kingdon 1974). Vocalizations include a loud chattering call (Thomas & Wroughton 1910).

Foraging and Food Vegetarian and occasionally insectivorous. Near L. Kivu, at the edges of the forest, the diet includes the fruits of several species of trees – *Parinari holstii*, *Syzygium cordatum*, *Conopharyngia holsteii*, *Carapa* sp. and *Urera hypselodendron* – as well as the lichen *Usnea* (Rahm & Christiaensen 1963). In farmlands and plantations, feed on guavas, papaya, bananas and palm nuts. Stomachs contained fragments of leaves, stems and insects. Local people say that these squirrels store food (Rahm & Christiaensen 1963).

Social and Reproductive Behaviour Usually seen alone or in pairs (Rahm & Christiaensen 1963).

Reproduction and Population Structure Little information. One pregnant ♀ with three large young found in Mar (Rahm & Christiaensen 1963).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Heliosciurus undulatus ZANJ SUN SQUIRREL

Fr. Héliosciure de Zanj; Ger. Zanj Sonnenhörnchen

Heliosciurus undulatus (True, 1892). Proc. U. S. Nat. Mus. 15: 465. 'Male. Mount Kilima-Njaro, 6000 feet (1800 m). Female. Kahé, south of Mount Kilima-Njaro'. Tanzania.

Taxonomy Originally described in the genus *Sciurus*. Considered a subspecies of *Heliosciurus rufobrachium* (e.g. Kingdon 1974) until separated from this species by Grubb (1982). Does not intergrade with the populations of *H. rufobrachium* to the south or west. The form *keniae*, included in this species by Kingdon (1974), is now retained in *H. rufobrachium* (Thorington & Hoffman 2005). Synonyms: *daucus*, *dolosus*, *marwitzi*, *shindi*. Subspecies: none (Grubb 1982). Chromosome number: not known.

Description Large tawny-grey squirrel with long ringed tail. Dorsal pelage grizzled tawny-grey; hairs banded black and orange, with white subterminal band. Ventral pelage whitish-grey to ochre. Face, nose and feet similar to dorsal pelage, but suffused with pale grey-ochre to orange-ochre. Tail long (ca. 120% of HB), slender, with 10–14 black bands alternating with pale bands, tail hairs ca. 40 mm. Pelage colour varies geographically (see below). Skull: cheekteeth ⁴/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle prominent. Nipples: not known.

Geographic Variation Individuals from higher altitudes are darker and richer in colour; those from the north of the range are paler, and those from the south are duller and greyer (Grubb 1982).

Similar Species

H. ruwenzorii. White ventral stripe; Rwenzori and Albertine Rift Valley only.

H. rufobrachium. Reddish colouration of ventral pelage, and on limbs; different distribution.

H. mutabilis. Darker colour, with seasonal changes in pelage colour; different distribution.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ (perhaps also northern parts of Coastal Forest Mosaic BZ). Recorded from SE Kenya and NE Tanzania, including Mafia and Zanzibar Is. Does not overlap with *H. rufobrachium* or with *H. mutabilis*. Occurs up to 1800 m on Mt Kilimanjaro.

Habitat No information.

Remarks Omnivorous. Fruits, seeds, palm dates, leaves, buds, with insects important seasonally (Kingdon 1997). Nests in hollow trees or branches.

Conservation IUCN Category: Data Deficient.

GENUS *Myosciurus* African Pygmy Squirrel

Myosciurus Thomas, 1909. Ann. Mag. Nat. Hist., ser. 8, 3: 474. Type species: *Sciurus minutus* Du Chaillu, 1860 (= *Sciurus pumilio* Le Conte, 1857).

Myosciurus is a monotypic genus, with restricted distribution in rainforests of Cameroon, Equatorial Guinea, Gabon and NW Congo. The most obvious character is the very small size ('not much bigger than a man's thumb' – Rosevear 1969) and the absence of any externally visible pollex (Digit 1 of forefoot). The skull is small, broad and rounded, with rounded orbits, semicircular zygomatic arch, large auditory bullae, and narrow rostrum (Figure 13). Masseteric tubercle absent. Dental formula is $I^{1/1}, C^{0/0}, P^{1/1}, M^{3/3} = 20$.

Myosciurus pumilio.

Figure 13 Skull and mandible of *Myosciurus pumilio* (BMNH 5.5.23.25).

Pygmy squirrels similar in size to the African *Myosciurus* are found in South America and the East Indies. The remarkable similarity between these forms is thought to be the result of convergent evolution, and does not to imply any close phylogenetic relationship

between them (Rosevear 1969). There is a single species, *Myosciurus pumilio*.

Louise H. Emmons

***Myosciurus pumilio* AFRICAN PYGMY SQUIRREL**

Fr. Écureuil pygmée; Ger. Afrikanischer Zwerghörnchen

Myosciurus pumilio (Le Conte, 1857). Proc. Acad. Nat. Sci. Philadelphia 9: 11. 'headwaters of the Ovenga River', Gabon.

Taxonomy Originally described in the genus *Sciurus* (Rosevear 1969). Synonyms: *minutulus*, *minutus*. Subspecies: none. Chromosome number: not known. See also Gharaibeh & Jones (1996).

Description Very small rufous-brown squirrel, about the size of a mouse. Pelage soft, of moderate length. Dorsal pelage rufous-brown, grizzled with buff; hairs dark grey or black at base, rufous-red or yellowish-red terminally. Ventral pelage pale brown. Head similar to dorsal pelage, with prominent pale buff eye-ring. Ears brown, with inner and outer margins bright pale buff. Fore- and hindfeet elongated and narrow; forefeet with no external evidence of a Digit 1, although the vestigial, much reduced bones persist within the wrist (Emmons 1979b). Tail moderate (ca. 86% of HB), slender, hairs rufous at base tipped with black above. Tail is held straight out behind the body, never over the back. Skull: incisors slightly proodont; cheekteeth $4/4$; posterior end of bony palate slightly posterior to M^3 ; masseteric tubercle absent. Nipples: $0 + 0 + 1 + 1 = 4$.

Geographic Variation None recorded.

Similar Species No other squirrel in Africa is as small as this species. The next largest squirrel is *Paraxerus alexandri* (HB: 102.5 [91–114] mm, T: 110.3 [93–126] mm).

Myosciurus pumilio

Distribution Endemic to Africa. Rainforest BZ (West Central Region, parts of Eastern Nigerian and Gabon sub-regions). Recorded from S Cameroon, NW Congo, Equatorial Guinea (Rio Muni and Bioko I.) and Gabon. There is no evidence that the species occurs in eastern Nigeria (see Happold 1987).

Habitat Restricted to evergreen moist rainforests and secondary forests. Uses all levels of the vegetation from near the ground to the canopy, but mostly uses 0–5 m (Emmons 1980).

Abundance Mostly rare, with a patchy distribution and small geographic range. May be fairly common in some localities.

Adaptations Diurnal and arboreal. The tiny body size is probably an adaptation to a specialized life-style of feeding on both the top and bottom surfaces of large tree trunks and branches. The elongated toes and the loss of Digit 1 on both fore- and hindfeet appear to be adaptations associated with a lizard-like locomotion, with the long limbs splayed sideways and the body flattened against the substrate, held by the hooked claws (Emmons 1979b). The nest is undescribed, but individuals have been seen entering tree holes.

Foraging and Food Omnivorous. African Pygmy Squirrels have a highly specialized foraging behaviour. They forage almost incessantly, moving rapidly over the surfaces of tree trunks and branches, pulling off small chips of bark, and holding them in the forepaws while something is scraped with the teeth from the bark surface before the chip is dropped. Three stomach contents included bark scrapings (30%), fruit (33%) and ants and termites (37%). The nutritive material sought from bark is unidentified, and it may be a bacterial or fungal film (Emmons 1979b, 1980). The Neotropical Pygmy Squirrel *Sciurillus pusillus* and Bornean Pygmy Squirrels *Exilisciurus exilis* and *E. whiteheadi* have virtually identical behaviour; they feed on a yellow material, probably fungus or bacteria growing on exudate, under the bark of particular species of living trees, especially certain legumes (Emmons & Feer 1997, L. Emmons unpubl.). In contrast, African Pygmy Squirrels forage on the surface of bark pulled from both dead and living trees. These squirrels, unlike many other squirrels, are not known to cache food.

Social and Reproductive Behaviour Pygmy Squirrels are apparently solitary: they are usually sighted alone (87%; $n = 45$ observations) and only rarely are two active on the same tree (13%). The simple alarm call is a low amplitude pipping sound consisting of widely spaced short (18 ms, $n = 14$) pulses, which are emitted repeatedly (mean interval between pulses 279 ms, $n = 12$) (Emmons

1978). The squirrel usually does not stop foraging when it calls. The tail is carried stiffly straight behind the body when the squirrel is calling and its base is twitched from side to side, while the tip stays more or less centred. Because these squirrels spend most of their time splayed against trunks (and only the dorsal surface is normally seen), the side-to-side tail movement is an effective display.

Reproduction and Population Structure Embryo number: 2 (n = 1; Emmons 1979a).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern. Previously considered as 'Vulnerable'.

GENUS *Paraxerus*

Bush Squirrels

Paraxerus Forsyth Major, 1893. Proc. Zool. Soc. Lond. 1893: 189. Type species: *Sciurus cepapi* A. Smith, 1836.

Paraxerus alexandri.

A genus of very small to medium-sized tree squirrels with 11 species widely distributed over much of Africa south of the Sahara, except for arid areas and savanna habitats north of the Rainforest BZ. All species are arboreal; most species live in rainforest or montane forests, but two live in wooded savanna habitats. The genus is best represented in eastern Africa, where nine species are recorded. Most species are geographically and/or ecologically separated.

The genus is characterized by very small to medium size (HB: 91–114 mm for the smallest to 145–203 mm for the largest species), and a long well-haired tail mostly longer than the head and body. Pelage markings and colouration show considerable variation. The muzzle is slightly elongated, and the ears are mostly relatively longer than in *Funisciurus* and *Heliosciurus* (as expressed by percentage of GLS). Depending on the species, there is no side-stripe, one side-stripe or two side-stripes, and the side-stripes are pale or dark. Females have three pairs of nipples (for those species in which the number has been recorded). The skull is similar to that of *Funisciurus*

Figure 14. Skull and mandible of *Paraxerus cepapi* (HC 2172).

but without the specialized condition of the cheekteeth. There are five subhypsodont upper cheekteeth and four lower cheekteeth, all with prominent cusps; the posterior end of the bony palate is in line with the posterior end of M³; supraorbital foramen absent, and the masseteric tubercle is small and insignificant (Figure 14). Dental formula: I ¹/₁, C ⁰/₀, P ²/₁, M ³/₃ = 22 (cf. *Heliosciurus*).

Ecological characteristics of species in the genus also show considerable variation. Three species (*P. alexandri*, *P. boehmi*, *P. peoensis*) live in rainforest, four species (*P. cooperi*, *P. lucifer*, *P. vexillarius*, *P. vincenti*) live in montane forests, two species (*P. flavovittis*, *P. palliatus*) live in the coastal forests and neighbouring savannas of eastern Africa, and two species (*P. cepapi*, *P. ochraceus*) live in savanna woodlands. Likewise, diet and reproductive characteristics also

exhibit considerable variation. The ecology of most of these species is poorly known.

Paraxerus, *Funisciurus* and *Myosciurus* form a monophyletic clade. *Paraxerus* is related to *Funisciurus*, and the species of *Paraxerus* are more variable in ecology, size and in the number of transverse septae than *Funisciurus* species. From external appearance and habitat, Kingdon (1974) thought *F. carruthersi* was more like species of *Paraxerus* (*P.*

Courtship behaviour of *Paraxerus palliatus*.

| <i>P. flavovittis</i> | One, white, bordered ventrally by black | None | 172 | 39 | n. d. | SE Kenya to N Mozambique; savannas and forests |
| <i>P. boehmi</i> | Two, black, separated by yellow | None | 120 | 30 | 35 | Rainforest BZ (East Central Region) and relicts to N Zambia; edges of ears not white; mid-dorsal colour tawny-brown |

^a *P. palliatus bridgmani*; *P. p. ornatus* is ca. 20% larger in all measurements.

cooperi, *P. vexillarius*) than other species of *Funisciurus*, and considered *Paraxerus* to be a subgenus of *Funisciurus*. *Paraxerus* has in the past been confused with *Heliosciurus*. Ellerman (1940), for example, included *Heliosciurus ruwenzorii* and species of *Paraxerus* (*P. poensis*, *P. lucifer*, *P. vexillarius*) in a subgenus (*Aethosciurus*) of *Heliosciurus*. The skulls of the two genera (*Paraxerus* and *Heliosciurus*) are superficially similar but are distinguished by absence of the supraorbital foramen and small insignificant masseteric knob in *Paraxerus* (cf. supraorbital foramen present and large masseteric knob in *Heliosciurus*) and the form of the naso-premaxillary suture. *Paraxerus* can also be differentiated from *Heliosciurus* (Ellerman 1940) by the form of the zygomatic plate, which is shorter with the ridge stopping abruptly over the infraorbital foramen, and not approaching the superior border of the rostrum in *Paraxerus* (cf. zygomatic plate more strongly ridged, ridge

extending forward in *Heliosciurus*); and by the cheekteeth, which are usually more cuspidate in *Paraxerus*, especially in the lower tooth row, though *P. poensis* is conservative and resembles *Heliosciurus*.

Relationships of the genus have recently been re-assessed. Moore (1959) placed the genus in the tribe Funambulini (with non-African genera), whereas Thorington & Hoffmann (2005), on the basis of molecular studies by Mercer & Roth (2003) and Steppan *et al.* (2004), place it in the tribe Protoxerini with all the other African squirrels (except *Xerus* and *Atlantoxerus*).

Species in the genus are distinguished by size, presence/absence of side-stripes, presence/absence of reddish colouration of pelage, and habitat (Table 13).

Peter Grubb

Paraxerus alexandri ALEXANDER'S BUSH SQUIRREL

Fr. Écureuil de brousse d'Alexander; Ger. Alexander Buschhörnchen

Paraxerus alexandri (Thomas and Wroughton, 1907). Ann. Mag. Nat. Hist., ser. 7, 19: 376. Upper Welle, River Iri, Gudima, DR Congo.

Taxonomy Originally described in the genus *Funisciurus*. Referred to as *Tamiscus alexandri* by Rahm (1966, 1970). Synonyms: none. Chromosome number: not known.

Description Very small, snub-nosed, greenish-brown squirrel with white edges to ears and five long stripes on back and flanks. Dorsal pelage grizzled yellow, black and grey, giving appearance of greenish-brown at a distance; hairs dark grey at base, subterminal band yellow, usually with black tip. Some long pure black guard hairs. Wide tawny-orange mid-dorsal stripe from shoulders to mid-back bordered on each side by a thin black stripe and a thin creamy-yellow stripe. Ventral pelage similar but paler than dorsal pelage, often with irregular patches and streaks of yellow; hairs dark grey at base, yellow or buff at tip. Head similar in colour to dorsal pelage. Vibrissae long. White eye-ring around eye; not obvious in some individuals. Edges of ears finely covered with short white hairs. Limb extremities proportionally large compared with other small squirrels. Forelimbs greenish-brown; four slim long digits each with thin long sharp claw. Hindlimbs greenish-brown, with five digits, Digit 1 reduced; digits and claws similar to forelimbs. Tail long (ca. 100% of HB), well covered with short hairs, indistinctly marked with irregular brown and ochre bars, tapered towards tip. Seasonal changes in intensity of colouration (due to seasonal moulting or to fading?) have been noted: specimens collected between Nov and Feb were brighter than those in Apr, May and Sep. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

P. boehmi. Slightly larger; tawny-orange mid-dorsal stripe from shoulders to rump, bordered on each side by two black stripes separated by a yellow or cream stripe; ears pigmented without white hairs; comparatively longer nose; relatively smaller fore- and hindfeet.

Paraxerus alexandri

Funisciurus lemniscatus. Slightly larger, longer-nosed squirrel of darker overall colour. Dull brown mid-dorsal stripe bordered on each side by two black stripes from base of neck to rump, the outer stripe separated from the inner stripe by a pale yellow stripe; longer, more strongly patterned tail.

Distribution Endemic to Africa. Rainforest BZ (East Central Region) and parts of Eastern Rainforest–Savanna Mosaic. Recorded from NE DR Congo and Uganda. Distribution extends (east to west) from the Victoria Nile to the Lualaba R., and (north to south) from the Mbomou R. to the Lukuga R., at altitudes of 500–1500 m.

Habitat Lowland rainforest with a preference for tall relatively mature forest. Apparently common in Ironwood *Cynometra alexandri* (Caesalpinaceae), a climax species that forms extensive, nearly monospecific stands in many parts of its geographic range. Sometimes occurs in abandoned plantations within the rainforest in E DR Congo (Rahm 1970).

Abundance Commonly seen in mature forests. Locally, populations may be dense. Rare or absent in young forests regenerating after felling.

Adaptations Arboreal and diurnal. Alexander's Bush Squirrels have a compact body, with relatively large hands and feet, sharp claws and thin relatively long digits enabling them to scuttle, spread-eagled, over the very extensive surfaces of large forest trees. There is some indication that they prefer smoother types of bark. They are commonly seen on the bare surfaces of boles and large branches of very large forest trees such as Ironwood, Mahogany, Khaya and Mututu *Klainedoxa*, and may be seen emerging from hollow branches. It is uncertain whether they build nests or live in holes in trees. They live at many levels of the forest, but more often on larger branches than other squirrels. The reduced nasal region suggests that they rely less upon scent than most other species of squirrels, and they appear to be able to find scent clues only at very close quarters. The incisors are relatively small, suggesting a poor ability to gnaw; this is consistent with a diet of micro-fauna and flora (see below).

Foraging and Food Omnivorous. Commonly seen moving in fits and starts over the surfaces of branches. Food appears to be found at many levels of the forest but apparently not normally in the leafy canopy. Movements are fast, and a foraging squirrel explores continuously, stopping only briefly to consume the food items it encounters. Alexander's Bush Squirrels mostly forage alone, perhaps because of the dispersed nature of their food supply. The diet includes small ants and other insects (about 50% in a small sample). The exact composition of plant matter (such as that retrieved from stomach contents) has yet to be determined. It is possible that lichens may be a significant part of their diet. Traces of tree resins have been recorded (Kingdon 1974; J. Kingdon unpubl.). The diet is more insectivorous than that of sympatric *Funisciurus pyrrhopus* (Rahm 1970).

Social and Reproductive Behaviour Commonly seen alone but not infrequently in pairs. Larger numbers have not been noted. Typically silent, but may be the originator of a sharp, rather bird-like twitter sometimes heard when Alexander's Bush Squirrels are nearby. The large, mobile and white-coloured ears suggest that ear movements might be significant during social interactions.

Reproduction and Population Structure In E DR Congo pregnant ♀♀ have been recorded in Mar, Apr, Jul and Sep (Rahm 1970). In Uganda, pregnant ♀♀ were taken in Sep and Nov and juveniles in Apr, Oct and Nov (Kingdon 1974). Embryo number: usually one, sometimes two (Rahm 1970). Testes of specimens collected in Uganda vary in size; whether fluctuating testis size follows a seasonal trend has yet to be determined.

Predators, Parasites and Diseases The most likely predators are accipiterine hawks but hornbills perhaps represent a hazard, especially for animals sheltering in crevices or nests. Snakes may also be predators occasionally. Ectoparasites have not been noted by collectors.

Conservation IUCN Category: Least Concern.

Previously considered as Near Threatened. The habitat is declining in area due to logging of forests.

Paraxerus boehmi BOEHM'S BUSH SQUIRREL

Fr. Écureuil de brousse de Boehm; Ger. Boehms Buschhörnchen

Paraxerus boehmi (Reichenow, 1886). Zool. Anz. 9: 315. 'Marungu (Inner-Afrika)' (= Marungu, SE DR Congo).

Paraxerus boehmi.

Taxonomy Originally described in genus *Sciurus*. One form, provisionally treated here as a subspecies (*P. b. vulcanorum*, see below) has, with some justification, been regarded as a separate species by some authorities (e.g. Schouteden 1946, as *Tamiscus vulcanorum*). This interesting situation deserves further study in the field, supplemented by molecular work to determine whether more than one species is involved. Referred to as *Tamiscus emini* by Rahm (1966) and Rahm & Christiaensen (1963). Synonyms: *antoniae*, *emini*, *gazella*, *lunaris*, *tanganyikae*, *ugandae*, *vulcanorum*. Subspecies: four. Chromosome number: not known.

Description Small olive-coloured squirrel with five long stripes. Pelage varies geographically (see below). Dorsal pelage grizzled yellow, black and grey giving appearance of olive or greenish-brown at a distance. Wide mid-dorsal stripe, tawny-orange, from shoulders to rump, bordered on each flank by two black side-stripes separated by white or cream (giving the impression of an additional stripe). Ventral pelage paler than dorsal pelage. Head similar in colour to dorsal pelage with three pale longitudinal stripes (sometimes indistinct): one above and below each eye, and one across cheek. Ears small, rounded, deeply pigmented, and without white hairs. Fore- and hindlimbs greenish-brown; forelimb with four digits, each with thick claw; hindlimb with five digits each with sharp thick claw. Tail long (ca. 125% of HB), well covered with short hairs; mottled black and ochre and indistinctly barred; tapers towards tip. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: not known.

Geographic Variation Pelage colour and pattern of stripes vary geographically. Lowland and upland forms meet and reportedly overlap in range at about 2000 m. Four subspecies are recognized:

- P. b. boehmi*: lowland forest west of Albertine Rift Valley. Pelage darker and sparse; white stripe conspicuous (see Description above).
- P. b. emini*: lowland forest east of Albertine Rift Valley. Pelage paler and sparse; white stripe conspicuous.
- P. b. gazellae*: lowland forest margins in S Sudan. Pelage paler, somewhat 'bleached', but otherwise resembles *P. b. boehmi*.
- P. b. vulcanorum*: montane forests of the Albertine Rift (Rwenzori Mts and the mountains between L. Edward and L. Tanganyika). Pelage darker olive/russet, dense and long; upper black side-stripe wide; lower black side-stripe narrow, white stripe (in between the black side-stripes) narrow and not conspicuous. This subspecies may be a distinct montane species (J. Kingdon unpubl.).

Similar Species

- P. alexandri*. Very small (smaller than *P. boehmi*); wide tawny-orange mid-dorsal stripe from shoulders to mid-back bordered on each side by thin black stripe and thin creamy-yellow stripe; vivid white ears; relatively larger fore- and hindfeet.
- Funisciurus lemniscatus*. Slightly larger, mainly terrestrial squirrel of darker overall colour. Dull brown mid-dorsal stripe (but redder than in *P. boehmi*) bordered on either flank by two black stripes from base of neck to rump, the outer stripes separated from inner stripes by pale yellow band; longer, more strongly patterned tail.

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Recorded from E DR Congo, Uganda, S Sudan, NW Tanzania and N Zambia. The range of subspecies *P. b. vulcanorum* includes the montane forests of the Albertine Rift Valley. Records from W Kenya need confirmation. An outlier population is present in Bahr el Ghazal (at two localities west of Malek) in C Sudan (F. Dieterlen unpubl.).

Habitat Typically found in the undergrowth and lower storeys of rainforest, notably in thick tangles of lianas and sometimes on the ground. The montane form prefers disturbed areas with dense undergrowth. Although mainly a true rainforest species it has

Paraxerus boehmi

been recorded from wooded savanna in E DR Congo (Rahm & Christiaensen 1963), as well as on the edges of plantations and in tangles along roadsides (Rahm 1966).

Abundance Common in suitable habitats. The subspecies *P. b. vulcanorum* is especially common in montane areas.

Adaptations Arboreal and diurnal. Boehm's Bush Squirrels are well adapted to moving fast through dense tangles of vegetation by virtue of their tapered limbs and small hands and feet. They can travel in any direction over trunks and branches, even hanging upside-down to examine the underside of branches. The inner toe of the hindfoot is partially opposable, increasing the squirrel's ability to grip plant stems and twigs. The robust muzzle and incisor teeth are well suited to tearing bark, moss and lichen and, it seems, to catching, gnawing and carrying food items.

Boehm's Bush Squirrels make unusually large nests (which resemble the nests of birds) that are dense agglomerations of fine twigs and grasses with a chamber in the middle lined with finer materials, including strands of soft shredded bark. They are built in thick tangles 2–8 m from the ground (Rahm & Christiaensen 1963).

As with some other squirrels, the tail is likely to serve as a scent disperser for pheromones emanating from the anal glands. Sustained flicking of the tail is often accompanied by a bird-like chitter. This has been interpreted as an alarm but is just as likely to serve as a combined olfactory/auditory/visual set of signals directed at conspecifics.

Foraging and Food Frugivore and insectivore. Animals forage by travelling along branches, tearing moss, lichen and bark with their incisor teeth. However, unlike other species of squirrels, the forefeet seem to be less commonly used to hold food, which is usually seized by the mouth. Of 30 stomachs investigated in Uganda, seven contained insects alone (mainly ants but also caterpillars and beetles), ten contained a large proportion of insects, while eight

had traces of insects; 12 contained vegetable matter (including the fruits of *Rubus* and epiphytic mushrooms) and ten contained large quantities of tree resin (Kingdon 1974). In E DR Congo, stomach contents contained resins from *Albizzia* trees, and the remains of fruits, caterpillars, beetles and other insects (Rahm & Christiaensen 1963). Feeding on insects is unusual for squirrels.

Social and Reproductive Behaviour Normally solitary, but also observed in pairs and trios. Boehm's Bush Squirrels sometimes forage close to another individual for some time. They never aggregate, but the regularity of sightings suggests that they remain fairly evenly dispersed, and perhaps are more densely distributed in suitable habitats. Reproductive ♂♂ pursue ♀♀ relentlessly, and copulation has been seen even while hanging on a vertical trunk.

Reproduction and Population Structure In E DR Congo, where rainfall occurs in all months, Rahm (1970) recorded reproductively active and pregnant ♀♀ in all months of the year. The percentage of pregnant ♀♀ varied monthly from 10 to 35% (total n = 222 ♀♀ examined, range 8–41 ♀♀/month) with the highest percentages occurring towards the end of the dry season and the beginning of the wet season. Rahm (1970) commented that rainfall did not seem to exert a strong influence on the timing of reproduction. In Uganda, Kingdon (1974) provided confirmatory evidence, with records of pregnant ♀♀ in Jan, Jun, Nov and Dec (total n = 4), and lactating ♀♀ in Jan, May, Jun and Jul (total n = 5). Embryo number: 1 (90%) or 2 (10%) (n = 61 pregnant ♀♀; Rahm 1970). This pattern of reproduction indicates that the population contains young, subadult and adult individuals, and reproductively active and inactive individuals, in all months of the year.

Predators, Parasites and Diseases The most likely predators are accipiterine hawks (especially the Long-tailed Hawk), hornbills and snakes. They might also be vulnerable to nocturnal arboreal carnivores such as *Genetta* spp. and Palm Civet *Nandinia binotata*, especially while in their nests. They are host to a particular coccidial parasite, *Wenyonella parva* (Van den Berghe 1938).

Conservation IUCN Category: Least Concern.

Paraxerus cepapi SMITH'S BUSH SQUIRREL

Fr. Écureuil de brousse de Smith; Ger. Smiths Buschhörnchen

Paraxerus cepapi (A. Smith, 1836). Report on the Expedition and Exploration of Central Africa, p. 43.

Marico River, Rustenberg District, W Transvaal, South Africa.

Taxonomy Originally described in the genus *Sciurus*. Kingdon (1974) proposed that *Paraxerus cepapi* and *Paraxerus palliatus* hybridize in the wild and form hybrid populations; Viljoen (1989) disagreed, pointing out distinctive differences in behaviour and habitat use between the two species. Many subspecies have been described: Amtmann (1975) lists ten subspecies although recognizing that not all of them are valid, and Ansell & Dowsett (1988) subsequently synonymized *soccatus* with *yulei*. Synonyms: *cepate* (lapsus for *cepapi*), *bororensis*, *carpi*, *cepapoides*, *chobiensis*, *kalaharicus*, *maunensis*, *phalaena*, *quotus*, *sindi*, *soccatus*, *yulei*. Subspecies: nine. Chromosome number: not known.

Description Medium-sized yellowish-brown grizzled squirrel without any bright colours or markings. Dorsal pelage and flanks grey, yellowish-brown or brown; hairs annulated with alternating bands of yellow and black, usually with black tip. Ventral pelage dull white, tending to yellow or buff on the chest. No side-stripe. Head with indistinct upper and lower white eye-stripes; cheeks pale yellowish-brown. Limbs short, similar in colour to flanks; well-developed digits with sharp claws. Tail long (ca. 95% of HB), bushy, with long

hairs annulated with alternating bands of black and yellowish-brown. Pelage colour varies geographically. Skull: cheekteeth ⁵/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 0 + 1 + 1 + 1 = 6.

Geographic Variation Amtmann (1975) lists the following subspecies (see also above):

P. c. bororensis: Namabieda, Boror, north of the Zambezi R., Mozambique. Darker and more chestnut than *P. c. cepapoides*. Sides of body and lower part of hind legs greyer.

P. c. carpi: Junction of Messenguez and Zambezi rivers, Mozambique. Small size (HB: 158 mm; T: 150 mm). Paler than *P. c. cepapi*, with thighs and mid-line of underside of tail orange-yellow, feet whitish or whitish-yellow.

P. c. cepapi: Transvaal, S Botswana and S Zimbabwe. See Description.

P. c. cepapoides: Zimbiti, Beira, Mozambique. More rusty coloured than *P. c. cepapi*, with the upper parts of body and thighs having a more tawny hue.

- P. c. chobiensis*: N Botswana and N Namibia. Ventral pelage and toes whiter than in *P. c. cepapi*.
- P. c. phalaena*: Ovamboland, Namibia, and SW Angola. Dorsal pelage pale grey, with crown, shoulders, hips and legs also grey. Fore- and hindfeet pale buffy-white, paler than in *P. c. cepapi*.
- P. c. quotus*: SE Katanga and N Zambia. Darker colouring with no suffusion of colour on flanks.
- P. c. sindi*: Tete district, Zambezi R., Mozambique and S Malawi. Thighs and underside of mid-line of tail ochre. Ventral pelage white.
- P. c. yulei*: NE Zambia, N Malawi and W Tanzania. A large subspecies (type specimen HB: 205 mm). Dorsal colour pale coarsely grizzled tawny, greyer over the shoulders, sides paler greyish-tawny; ventral colour white, more greyish on the belly; fore- and hindfeet greyish-white to whitish-yellow.

Similar Species

- P. ochraceus*. Darker, with many white-tipped hairs in dorsal pelage; mostly in E Tanzania and Kenya (further north than *P. cepapi*).

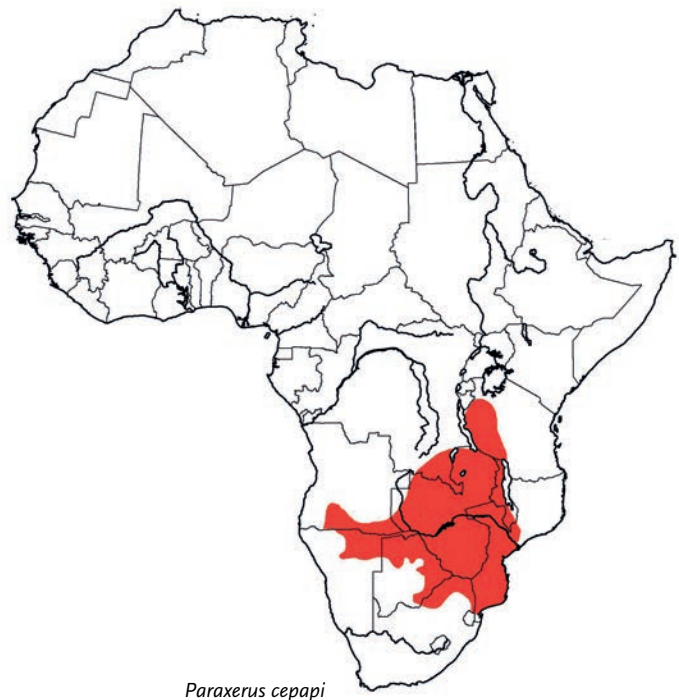

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded from S Angola, Zambia, SE DR Congo, Malawi, SW Tanzania, S Mozambique, N Namibia, N Botswana, Zimbabwe and South Africa (former Transvaal).

Habitat Mixed woodlands and thickets, especially in stony, hilly country, especially in *Colophospermum* (mopane), *Brachystegia* (miombo) and *Acacia* woodlands, and in riverine forests. These squirrels prefer areas where there are trees with suitable holes for nesting.

Abundance Widespread and fairly common. In sandveld habitat in South Africa, density was 2.08–2.58 individuals/ha (biomass of 449–557 g/ha) (Viljoen 1986).

Adaptations Diurnal and arboreal. Smith's Bush Squirrels avoid activity during the hottest times of the day. Winter mornings usually begin with basking and grooming in the sun. Both auto- and allogrooming are significant social behaviours (see below). They are very alert and can be quick on the ground and swift in the trees when danger is near. Although mainly arboreal, individuals will descend to the ground to forage for fallen fruits. They are very active, running quickly along branches and jumping from tree to tree. At night, squirrels retire to their holes, where they nest in territorial groups. While holes in trees are favourite nest sites, they will also nest in holes in the ground, in rocky crevices and in roofs of houses. Nests are lined with grass and leaves, and the squirrels frequently clean them out, possibly to reduce the number of parasites in the nest (Smithers 1983).

Foraging and Food Predominantly vegetarian; sometimes omnivorous. Bush Squirrels forage in the trees and on the ground, and suitable foods are held in the forefeet while eating. In South Africa (Viljoen 1977b) they feed opportunistically on a wide variety of seeds, berries, flowers, stems, leaves and gum, changing the diet according to the season. Seeds and gums of *Acacia*, and seeds and flowers of *Aloes* are favourite foods. Analysis of stomach contents showed that insects (mostly termites) formed about 30% of the diet on an annual basis (range 0–85%), and 79% of stomachs ($n = 49$) contained some insect material. Over a period of several

Paraxerus cepapi

months, more than 30 species of plants were utilized in the diet (Viljoen 1975). In East Africa, they are reported to feed on fruits of *Sclerocarya*, *Pterocarpus* and *Kigelia*, *Aloe* and *Euphorbia* leaves, as well as unspecified bulbs, nuts, seeds, insects and bird's eggs (Kingdon 1974). In gardens and plantations, they feed on mangoes and many other cultivated fruits (De Graaff 1981). Seeds are cached close to grass tufts and tree trunks, thus facilitating dispersal and germination of savanna trees (Viljoen 1997). Smith's Bush Squirrels drink water, both in the wild and in captivity, usually from holes in trees (Viljoen 1975). Smith's Bush Squirrels are a 'colonizing species' (Viljoen 1983a), living in vegetation that grows quickly and produces many fruits and seeds (in contrast to tall mature forest); hence a squirrel can find sufficient daily food in a small area (see above).

Social and Reproductive Behaviour Social and territorial. Average group size is five animals (rather large for squirrels), usually including one or two adults and several juveniles. Group size in South Africa varied seasonally, from an average of 2/group in Sep to 12/group in Nov when adults were accompanied by young, and in different years (Viljoen 1977a). Pairs and solitary animals are commonly seen. They are territorial, except during the mating season when strange squirrels are tolerated. Territory size in termitaria thickets is 0.3–1.26/ha, although within this area an individual or group may feed within only 150 m² (Viljoen 1986, 1997). Territory size varies with habitat, being smallest in termitaria thickets and larger in woodlands. Territorial behaviour includes vocalizations, chasing of strangers and scent marking. Scent marking is very common and can include mouth-wiping, urination and anal-dragging (Viljoen 1983b).

A dominance hierarchy was observed by Viljoen (1977a), especially with regards to feeding and access to food. In captivity, individuals are very aggressive towards each other; fighting results in many torn ears and sometimes an individual is killed. Dominance–subordination relationships are important in the social organization of these squirrels, and hence behaviour such as chasing, fighting, mutual

grooming and scent-marking play important roles in maintaining group bonds and territorial boundaries.

Vocal communications are well developed (Viljoen 1983b). Most vocalizations begin with a loud call (usually a 'click', 'rattle' or 'whistle') and continue with decreasing intensity and descending pitch. Different types of calls may be joined in succession, depending on the circumstances. Four calls have been described: (a) Whistle call – a high frequency call, with 6–7 notes emitted at about 1 sec intervals; rather similar to a bird call, indicating extreme alarm. (b) Rattle and clicks, a series of different calls indicating alarm and alertness, and also used in territorial defence. These complicated calls results in 'chir-chir-chir' alarm rattles and clearer 'click-click-click' calls, spread out over several seconds. (c) Murmurs – a low-pitched nasal sound emitted during courtship and mating by the male. Clicking noises are also emitted by both ♂ and ♀ during courtship, and by ♀ when communicating with young. (d) Grunting and growling – when disturbed at the nest.

Mating behaviour occurs in the morning. Mating chases are initiated by enthusiastic calls of ♀, a sound similar to the alarm rattle; ♂ also has a distinct mating call, and clicking and tail flicking are common in both sexes. Male allogrooms ♀ during mating, and they both autogroom afterwards (Viljoen 1977a).

Reproduction and Population Structure In Botswana, pregnant ♀♀ recorded in every month except May and Sep (n = 256 ♀, Smithers 1971); the number of pregnant or lactating ♀♀ was significantly lower during the cold dry months (4.5%) than during the warm wet months (51%). In South Africa, reproduction is seasonal and most young are born in Oct–Jan (Viljoen 1997). While one litter/year is most common, inter-birth interval in captive animals is 60–63 days (n = 4; Viljoen, 1977a). Gestation: 56–58 days (longer than for most squirrels). Litter-size: 2 (1–3), sample size not recorded. At birth, young are comparatively precocious. Eyes open by Day 7–8, young begin to climb out of the nest by Day 19, take solid food by Day 21 and are fully weaned by Day 29–42.

Sexual maturity by 6–10 months. Both parents groom their young. Subadults are usually evicted from the group when sexually mature. Infanticide has been observed occasionally by ♂♂ in a group, after which ♂♂ may try to mate with ♀♀ (De Villiers 1986).

Predators, Parasites and Diseases Predators probably include raptors, snakes and probably some carnivorous mammals. Ectoparasites include a species of chigger, two species of mites, seven species of ticks, four species of fleas and one species of sucking louse (details in De Graaff 1981). Blood parasites include several bacteria (transmitted by ticks), which are responsible for a variety of fevers. Viljoen (1977b) noted that all the squirrels she studied were heavily infected with the parasitic nematode *Syphacia paraxeri*.

Conservation IUCN Category: Least Concern.

Paraxerus cooperi COOPER'S BUSH SQUIRREL (COOPER'S MOUNTAIN SQUIRREL)

Fr. Écureuil de brousse de Cooper; Ger. Cooper Buschhörnchen

Paraxerus cooperi Hayman, 1950. Ann. Mag. Nat. Hist., ser. 12, 3: 262. Kumba Division, Rumpi Hills, Cameroon.

Taxonomy Although originally described in the genus *Paraxerus*, Rosevear (1969) placed this species (together with *poensis*) in the genus *Aethosciurus* even though he admitted that the status of the genus was questionable. Eisentraut (1976) placed *cooperi* in a separate genus, *Montisciurus*, because it has many palatal ridges between the molars. Synonyms: none. Chromosome number: not known.

Description Medium-sized dark squirrel with pale golden-rufous thighs. Pelage very soft and long. Dorsal pelage blackish-brown speckled with creamy-buff, becoming more olive-green and golden on flanks; dorsal hairs dark grey or black at base, subterminal band bright buff or gold, with black tip. Ventral pelage medium grey at base, golden-yellow at tip. Head similar to dorsal pelage. Ears darkly pigmented, mostly naked, with yellow-tipped hairs on outer surface. Lips and cheeks golden. Forearms, upper surface of forefeet

and hindfeet rufous. Thighs deep rufous. Tail long (ca. 100% of HB), blackish golden-green above, without bands or rings, golden-yellow stripe (similar in colour to ventral pelage) below. Skull: cheekteeth 5/4; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: not known.

Geographic Variation None recorded.

Similar Species

P. poensis. Smaller (HB: 148–161 mm), lacks rufous colour on limbs and feet.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from forested montane regions of S Cameroon (Kupe Mts, Oku Mts, Rumpi Hills; Eisentraut 1973).

*Paraxerus cooperi*

Habitat Lower storeys of forest remnants in the Bamenda highlands at altitudes above 1400 m (Rosevear 1969).

Abundance No information. In the late 1960s, the species may have been far more abundant than previously thought (M. Eisentraut in Rosevear 1969).

Remarks One individual (the holotype) was feeding on the succulent flowers of the guttiferaceous tree *Pentadesma butyracea* and was noticeably fat. This record is the only direct evidence of squirrels feeding on flowers in W Africa (Rosevear 1969).

Conservation IUCN Category: Data Deficient.
Previously considered as Vulnerable.

Paraxerus flavovittis STRIPED BUSH SQUIRREL

Fr. Écureuil de brousse rayé; Ger. Gestreiftes Buschhörnchen

Paraxerus flavovittis (Peters, 1852). Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 17: 274. 'Africa orientalis. Mossimboa, Quitangonha, a 11° ad 15° Lat. Aust'. Mocimboa, NE Mozambique.

Taxonomy Originally described in the genus *Sciurus*. Commonly spelled *flavivittis*, but this was an unjustified emendation by Peters (1852). Four subspecies usually recognized, but individual and seasonal variations suggest that *mossambicus* is a synonym of *flavovittis* (see Hinton 1920). Synonyms: *exgeanus*, *ibeanus*, *mossambicus*. Subspecies: three. Chromosome number: not known.

Description Medium-sized arboreal squirrel with a lateral whitish side-stripe. Pelage short and slightly coarse. Dorsal pelage rusty-brown or red-brown; hairs black with one or two wide rusty-brown bands, usually black at tip. White to yellowish side-stripe, 9–10 mm wide, bordered below by a darker stripe. Flanks (below dark side-stripe) olive-brown. Ochraceous hairs tint the forelimbs, and ochraceous colouration may extend across the shoulders forming a mantle, and even onto the crown and into the lumbar region. Ventral pelage white or off-white. Head similar to dorsal pelage, though usually not ochraceous. Cheek with two indistinct white bands, one above the eye and one below, from nasal region to base of ear. Fore- and hindfeet whitish. Tail long (ca. 97% of HB), bushy towards tip, with black and white rings at distal end. Pelage colour

varies seasonally or individually, and also during the moult. Skull: cheekteeth ⁵/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: not known.

Geographic Variation

P.f. exgeanus: SE Tanzania. Side-stripe narrower (5 mm wide) and not as long as in *flavovittis*.

P.f. flavovittis: NE Mozambique (Mossimboa). See Description above.

P.f. ibeanus: NE Tanzania and SE Kenya. Side-stripe slightly broader than in *exgeanus*, but shorter; facial stripes faint.

Similar Species

Paraxerus spp. (other striped species). Mostly smaller in body size.

P. cepapi. No side-stripe.

P. ochraceus. No side-stripe.

Distribution Endemic to Africa. Coastal Forest Mosaic BZ and nearby regions of Zambezian Woodland BZ. Recorded from SE Kenya, E and SE Tanzania, SE Malawi and N Mozambique.

Habitat Savanna and forest, especially where there are *Uapaca* trees, and hardwood trees with holes (suitable for nesting). May also occur in cultivations.

Abundance Common and widespread between the Rufigi and Rovuma rivers in Tanzania. Particularly numerous where there are many old hardwood trees (Kingdon 1974).

Adaptations Diurnal and arboreal. These squirrels nest in the holes and hollows of hardwood trees, and sometimes nest in the roofs of houses (Kingdon 1974).

Foraging and Food Omnivorous. Forages on the ground and in the trees. Feeds on fruits, seeds, buds, leaves, roots and some animal matter. In farmland, eats millet and other grains (Kingdon 1974, 1997).

Social and Reproductive Behaviour Little information. Usually seen in pairs or as ♀ with her young (Kingdon 1974).

Reproduction and Population Structure Young and juveniles have been recorded in Mar, Apr, Jun and Sep (Kingdon 1974). Young are born in nests inside hollow trees; one nest was made of coconut fibres and grass (A. Loveridge in Kingdon 1974). Both pale and dark side-stripes are present in young when HB 90–100 mm (labels, BMNH).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.
Previously considered as Least Concern.

Paraxerus lucifer BLACK-AND-RED BUSH SQUIRREL

Fr. Écureuil de brousse rouge et noir; Ger. Tanganjika-Buschhörnchen

Paraxerus lucifer (Thomas, 1897). Proc. Zool. Soc. Lond. 1897: 430. Kombe Forest, Misuku Mts, Malawi.

Taxonomy Originally described in the genus *Xerus* (*Paraxerus*). *Paraxerus lucifer* is closely related to three other species, *P. vincenti*, *P. palliatus* and *P. vexillarius*. Synonyms: none. Chromosome number: not known.

Description Large bright rufous squirrel, sometimes with blackish patch on back. Pelage long and dense. Dorsal pelage bright rufous or russet with large patch of rufous-black in centre of back; dorsal hairs dark grey on basal half, bright rufous on terminal half, with black tip; numerous long pure black guard hairs in centre of back. Flanks bright rufous; hairs pale grey on basal half, bright rufous on terminal half. Ventral pelage, throat and chest dove-grey; hairs dove-grey with silver or whitish tip. Crown of head, cheeks and chin similar to dorsal pelage. Forelimbs and hindlimbs very bright rufous. Tail moderately long (ca. 60% of HB), similar in colour to dorsal pelage; above hairs pale rufous

at base with subterminal black band and bright rufous tip; below hairs bright rufous without banding; tail bands very indistinct. Skull: cheekteeth ⁵/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 0 + 1 + 1 + 1 = 6.

Geographic Variation None recorded.

Similar Species

P. palliatus. Ventral pelage rufous.

P. vexillarius. Ventral pelage grey, limbs rufous, sometimes with orange tail tip; Kilimanjaro and Usambara Mts, Tanzania only.

P. vincenti. Ventral pelage and limbs rufous; Namuli Mountain, Mozambique only.

P. cepapi. Yellowish brown without any rufous colour; widespread.

P. flavovittis. Lateral whitish side-stripe.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from montane habitats in N Malawi (Misuku Hills, Nyika Plateau), SW Tanzania (Poroto Mts, Nkuka Forest) (Ansell 1978, Ansell & Dowsett 1988). Not yet found in the Mafinga and Makutu Mts of NE Zambia where it might be expected to occur (Ansell 1978).

Habitat Restricted to montane forests in isolated montane regions that have a high annual rainfall (Kingdon 1974).

Abundance Maybe numerous in some habitats (Kingdon 1974).

Adaptations Diurnal and arboreal. Tend to be rather noisy, with a loud and distinctive call.

Foraging and Food Omnivorous. May forage on the ground. The diet includes vegetable matter, fruit, nuts, termites and ants (Kingdon 1974).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure A single ♀ caught in Sep was both pregnant and lactating, indicating two litters in close succession. Of eight ♀♀ examined in Mar and Apr, none was reproductively active (Kingdon 1974).

Predators, Parasites and Diseases Ectoparasites reported: fleas of the genus *Libyastus* (Ansell & Ansell 1973).

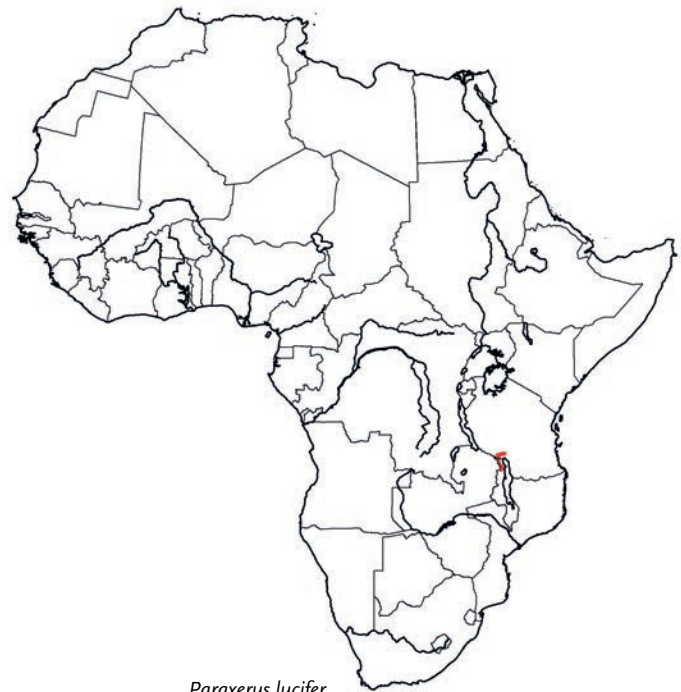

Conservation IUCN Category: Data Deficient.
Previously considered as Least Concern.

Paraxerus ochraceus OCHRE BUSH SQUIRREL

Fr. Écureuil de brousse ocre; Ger. Ockerfarbiges Buschhörnchen

Paraxerus ochraceus (Huet, 1880). Nouvelles Archives, Museum d'Histoire Naturelle, Paris, ser. 2, 3: 54. 'Cette petite espèce provient de Bagamoyo, station de nos missionnaires, sur côte de Zanguebar ...' Bagamoyo (06° 25' S, 38° 54' E), Tanzania.

Taxonomy Placed in genus *Funisciurus* (subgenus *Paraxerus*) by Kingdon (1974). Synonyms: *affinis*, *animosus*, *aruscensis*, *augustus*, *capitis*, *electus*, *ganana*, *jacksoni*, *kahari*, *pauli*, *percivali*, *salutans*. Amtmann (1975) recognized eight subspecies, but two of them were considered provisional; Kingdon (1974) recognized the five subspecies listed below. Chromosome number: not known.

Description Small squirrel with dull yellowish-brown pelage and slightly ringed tail. Dorsal pelage pale yellow, ochre or dark olive, grizzled. Pelage colour varies geographically (see below). Pale side-stripe in some subspecies. Ventral pelage yellow to off-white, not grizzled. Fore- and hindfeet same as dorsal pelage. Dorsal surface of fore- and hindfeet ochraceous. Tail long (ca. 100% of HB), with black and pale irregular bars and patches; tail is mostly held horizontally

behind the body. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: 0 + 1 + 1 + 1 = 6.

Geographic Variation Five subspecies recognized by Kingdon (1974):

P. o. aruscensis: NE Tanzania and SE Kenya. Pelage colour richer than

P. o. ochraceus, with a yellow ventral pelage; without a side-stripe.

P. o. electus: W Kenya. Pale form with white ventral pelage, perhaps without a side-stripe.

P. o. ganana: S Ethiopia, NE Kenya and Tana River area. Small, pale, sandy-yellow coloured race, without a side-stripe.

Paraxerus ochraceus.

P. o. jacksoni: S Kenya and most mountain forests in Kenya. The largest subspecies, generally darker than others with a rather green colouring and sometimes a pale side-stripe near the shoulder.

P. o. ochraceus: Central and E Tanzania. A medium-sized subspecies; mostly sandy grizzled ochre, ventral pelage off-white; distinct side-stripe.

Similar Species

P. cepapi. Ventral pelage paler. Occurs further south, and probably is not sympatric with *P. ochraceus*.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from Kenya and N Tanzania. Outliers in Somalia (near to Kenya/Ethiopian border) and in S Sudan.

Habitat Tolerant of many habitats; recorded from diverse wooded savannas, riverine forests in semi-arid regions, and thickets from near sea level to at least 2000 m. Also recorded from plantations (coffee, *Grevillea*, *Eucaplytus*) and in suburban gardens (e.g. in Nairobi).

Abundance Very common in some localities.

Adaptations Diurnal and arboreal. Most activity is in the early morning and late afternoon, with a rest period at the hottest time of the day. Ochre Bush Squirrels are very active, running quickly along branches and between the ground and the tops of trees. Calls include a high-pitched metallic ‘Burr’, which is emitted when threatened, accompanied by flicking of the tail.

Foraging and Food Mostly vegetarian. Forages in the trees and on the ground. The diet includes fruits, seeds, buds, flowers, roots, bulbs, *Acacia* gum and occasionally animal matter (Kingdon 1997).

Paraxerus ochraceus

Social and Reproductive Behaviour Live in pairs or small groups. Courtship involves a lot of chasing, mutual grooming and arching of the tail over the body.

Reproduction and Population Structure Little information. Observations in Kenya suggest that reproduction occurs in most months of the year. Litter-size: 2–3. Two ♀♀ with young may nest together. Young emerge from nest when 3–4 weeks of age. A mother may carry young in her mouth at times (A. Root in Kingdon 1974).

Predators, Parasites and Diseases Buzzards, snakes and genets are likely predators.

Conservation IUCN Category: Least Concern.

Paraxerus palliatus RED BUSH SQUIRREL

Fr. Écureuil de brousse à ventre roux; Ger. Rotbäuchiges Buschhörnchen

Paraxerus palliatus (Peters, 1852). Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 17: 273.

Mainland near Mocimboa do Ide, Mozambique I. 'Africa orientalis, Quintangonha, 15° Lat. Aust.'. Mozambique, near Mozambique I.

Taxonomy Originally described in the genus *Sciurus*. This species consists of a series of populations living in isolated forests. Kingdon (1974) suggested that some of the populations are hybrids between *Paraxerus cepapi* and *P. palliatus*, but Viljoen (1989) pointed out that this was unlikely because there are important differences between the species in behaviour and habitat. *Paraxerus palliatus* is closely related to three other species, *P. lucifer*, *P. vexillarius* and *P. vincenti*. The species exhibits considerable variation in pelage colour and pattern, such that Amtmann (1975) listed 11 subspecies but noted that this was probably an excessive number. Kingdon (1974) recognized three subspecies in the northern part of the range and Viljoen (1989) recognized four subspecies in southern Africa; all seven subspecies are recorded here. Body size and colouration seem to be influenced greatly by habitat, with larger darker squirrels in moist forest and smaller paler squirrels in dry forest (Viljoen 1989). The form *vincenti*, recognized as a valid species here, was classified as subspecies (*P. p. vincenti*) by Kingdon (1997). Synonyms: *auriventris*, *barawensis*, *bridgmani*, *freiei*, *lastii*, *ornatus*, *sponsus*, *suahelicus*, *swynnertoni*, *tanae*, *tongensis*. Subspecies: seven. Chromosome number: not known.

Description Medium to large arboreal squirrel with rufous or yellowish ventral pelage, variable geographically (see below, and Measurements). (Description for *P. p. palliatus*.) Dorsal pelage brownish, grizzled with buff. No side-stripes. Ventral pelage bright rufous. Crown of head grizzled brown, cheeks rufous. Fore- and hindlimbs, fore- and hindfeet rufous. Tail long (ca. 90% of HB), bushy, grizzled brown at base, bright rufous on terminal two-thirds. Individuals in drier climates are smaller (mean 210 g) than those in humid climates (mean 380 g). Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: 0 + 1 + 1 + 1 = 6.

Geographic Variation

- P. p. tanae* (including *barawensis*): S Somalia, E Kenya and N Tanzania (south to Pangani R.). Tail completely rufous-orange.
- P. p. freiei* (including *lastii*): Mafia and Zanzibar Is. Similar to coastal populations of *P. p. palliatus*, but with black feet.
- P. p. palliatus* (including *suahelicus*): E coastal Tanzania and N Mozambique. See Description above.
- P. p. swynnertoni*: Chirinda Forest, E Zimbabwe. Dorsal pelage grizzled black and buff; ventral pelage cinnamon-rufous. Face coloured like dorsal pelage, cheeks like ventral pelage. Colouration resembles *P. p. palliatus* and *P. p. ornatus*, but the different colouration of the face, fore- and hindfeet, and its smaller size, distinguishes it from these two.
- P. p. bridgmani* (including *auriventris* and *tongensis*): E coastal Mozambique (south of the Save R.). Dorsal pelage dark brown, grizzled; ventral pelage orange; generally paler and more 'yellowish' than other subspecies. (This may be a separate species – Amtmann 1975.)

*Paraxerus palliatus*

- P. p. sponsus*. Perhaps indistinguishable from *P. p. palliatus* with its brown dorsal pelage and bright rufous ventral pelage (see above), but geographically very close to *P. p. bridgmani*.
- P. p. ornatus*: South Africa (Ngoye Forest, Eshowe District, Zululand). Large; dorsal pelage dark brownish-black grizzled with buff; ventral pelage orange-rufous; tail dark brownish-black tinged with rufous.

Similar Species

- Paraxerus* spp. Without brightly coloured ventral pelage (i.e. not rufous, orange-rufous, yellowish).
- P. vincenti*. Similar in most respects, but restricted to Namuli Mountain, Mozambique.

Distribution Endemic to Africa. Coastal Forest Mosaic BZ of eastern Africa and some adjacent parts of the Zambezian Woodland BZ, especially extending inland along riverine forests and on some inland montane forests. Recorded from S Somalia, E Kenya, E Tanzania, Malawi, E Mozambique, E Zimbabwe and South Africa (KwaZulu–Natal), Mafia and Zanzibar Is. Some populations occur far inland along riverine forests (e.g. along the Tana and Ruaha Rivers; Kingdon 1974).

Habitat Dry to wet forests, preferring woodlands with shady thickets; dune forests and evergreen moist forests in Mozambique and South Africa. Montane populations up to about 2000 m (e.g. Mt Mlanje, Malawi).

Abundance Varies according to locality. In favoured habitats in South Africa, mean density was 4.32 squirrels/ha (*P. p. ornatus*) and 2.15 squirrels/ha (*P. p. bridgmani*) (Viljoen 1986). Biomass varies with locality: in Ngoye Forest (South Africa) was 1659 g/ha (maximum) and 595 g/ha in Mkwakwa Forest (Viljoen 1986).

Adaptations Diurnal and arboreal. Also spends a considerable amount of time on the ground, but the proportion of time spent foraging on the ground is uncertain. Nests in holes in baobabs and *Kigelia* trees.

Foraging and Food Omnivorous, feeding on seeds, fruits, nuts and invertebrates. Seems to prefer the seeds to the fleshy parts of the fruit. Viljoen (1983a) reported that captive squirrels ate raw liver and biltong. Drinks water when available, but does not appear to be dependent on it. Red Bush Squirrels are scatter hoarders of larger seeds, although they do not hoard large quantities of food as do squirrels of more temperate climates. They scratch under bark to get at insects, and Viljoen (1983a) reported that in captivity, they displayed hunting behaviour when stalking invertebrates.

Social and Reproductive Behaviour Although Red Bush Squirrels are quite common and diurnal, they are shy animals. Normally observed as solitary individuals or in pairs (Ansell & Dowsett 1988), although several squirrels may nest together in larger groups (mean 3.1 ± 1.2 ; Viljoen 1986). They nest in tree holes. Home-range varies according to habitat and sex: in evergreen moist forest, mean home-range (*P. p. palliatus*) was 3.18 ha ($\sigma^7 \sigma^7$) and 2.19 ha ($\sigma^7 \sigma^7$), and in coastal forest and thickets, mean home-range (*P. p. bridgmani*) was 4.17 ha ($\sigma^7 \sigma^7$) and 0.73 ha ($\sigma^7 \sigma^7$). Communication between animals is maintained by visual, auditory and olfactory signals. Viljoen (1983b) recorded lots of tail flicking and fluffing, especially in dense habitats. Vocalizations include an array of murmurs, hisses, growls, clicks, twitters and barks. Urine dribbling and anal dragging are also common. Males make murmuring vocalizations when chasing $\sigma^7 \sigma^7$. This may serve as a trigger to stimulate oestrus. Female builds nest in a tree hole lined with leaves. She keeps the nest very clean while young are being reared. When offspring are very young $\sigma^7 \sigma^7$ are extremely protective and respond aggressively toward intruders, including the male. Later, σ^7 , σ^7 and young form a family group. When young reach subadulthood (early winter in southern Africa), parents drive them away from the nest (Viljoen 1980).

Reproduction and Population Structure In the wild $\sigma^7 \sigma^7$ have 1–2 young/litter, and probably one litter/year. In captivity, multiple litters per year are possible. One lactating σ^7 recorded in March in S Kenya (Kingdon 1974). In southern Africa, young born during the warm wet season (Aug–Mar) (Smithers 1983). Gestation: 60–65 days. At birth, young weigh 13–14 g. Eyes open Day 7–10. Leave nest about Day 18. Weaned by Day 40 (Viljoen 1980).

Predators, Parasites and Diseases Uncertain, but it would be expected that snakes and arboreal mongooses would prey on young, and that hawks and raptors would be predators of adults.

Conservation IUCN Category: Least Concern.

Previously considered as Vulnerable.

Paraxerus poensis GREEN BUSH SQUIRREL

Fr. Petit Écureuil de brousse; Ger. Grünes Buschhörnchen

Paraxerus poensis (A. Smith, 1834). South Afr. Quart. J., 2nd ser., 2: 128. Fernando Poo (= Bioko I., Equatorial Guinea).

Taxonomy Originally described in the genus *Sciurus*. The species has been placed, at different times, in the genera *Aethosciurus*, *Heliosciurus*, *Funisciurus* and *Paraxerus*. Thomas (1916a) placed *poensis* into a new genus, *Aethosciurus*, citing molar differences to separate it from *Heliosciurus* and *Funisciurus*. Hollister (1919) placed it in *Heliosciurus* because of dental similarity, as did Ellerman (1940), who noted the similarity to *Paraxerus*. Moore (1959) placed it in *Funisciurus*, noting some cranial similarities. Rosevear (1969)

restored it to *Aethosciurus*, stating that it possessed characters of both *Heliosciurus* and *Funisciurus* and could not be placed unambiguously in either. Amtmann (1966) allocated the species to *Paraxerus*, even though its teeth differ from those of some members of that genus. Here, following Hoffman *et al.* (1993) and Thorington & Hoffman (2005), it is placed in the genus *Paraxerus* (see also Rosevear 1969 for a review). Synonyms: *affinis*, *musculus*, *olivaceus*, *subviridescens*. Subspecies: none. Chromosome number: not known.

Description Small, greenish-olive squirrel with a slender tail. Pelage soft, thick and dense. Dorsal pelage dark grizzled golden-green; hairs black at base with greenish-yellow tips. No lateral side-stripe. Ventral pelage pale yellow, thickly furred; hairs grey at base with long yellow tip. Cheek with yellow above and below eye, bordering a darker stripe to base of ear. Fore- and hindlimbs dark golden-green. Tail long (ca. 105% of HB), slender, not bushy, slightly darker than dorsal pelage. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: $1 + 0 + 1 + 1 = 6$.

Geographic Variation None recorded.

Similar Species

P. cooperi. Slightly larger (HB: 192–212 mm); rufous colour on fore- and hindlimbs; sympatric with *P. poensis* only in parts of Cameroon. *Myosciurus pumilio*. Much smaller, with inner and outer surface of ears white; sympatric with *M. pumilio* in west of range.

Distribution Endemic to Africa. Rainforest BZ except for eastern part of the East Central Region. Distributed in three disjunct populations: (a) from Sierra Leone to Ghana, (b) Cameroon, Equatorial Guinea (Rio Muni and Bioko I.), Gabon and Congo and (c) N DR Congo. *Paraxerus poensis* is the only small, greenish arboreal squirrel in its geographic range.

Habitat Lowland evergreen moist rainforests, secondary forest and tangles. Often seen in farmlands and plantations (Rosevear 1969).

Abundance Frequently seen.

Adaptations Diurnal and arboreal. Green Bush Squirrels are morphologically adapted for arboreal life, with short limbs and short, broad feet with strong, curved claws. Most observations

suggest they prefer vegetation above 5 m (Emmons 1980). Nests are undescribed; anecdotal reports suggest that Green Bush Squirrels build arboreal, exposed, leaf nests (Emmons 1979a) or nest in tree hollows (Rosevear 1969). In captivity, nest boxes were lined with finely teased fibres (Emmons 1975).

Foraging and Food Omnivorous. Forages arboreally. Six of 12 observations of foraging behaviour in the wild were of insect hunting by intense searching of stems, bark and arboreal crannies. In Gabon, the diet is mainly fruit and seeds (88% dry mass of stomach contents, $n = 8$) and arthropods (11%). The arthropods eaten are a miscellaneous mixture as might be expected from random searching (Emmons 1975, 1980). In captivity, Green Bush Squirrels were adept at capturing flying insects, which they pursued eagerly, and they opened and ate the eggs of small birds (Emmons 1975).

Social and Reproductive Behaviour Usually seen singly (68%, $n = 44$) or in pairs (18%) (Emmons 1980). The social organization is undescribed, but in captivity heterosexual pairs housed together showed extreme cohesion and many bonding behavioural characteristics (e.g. always sharing a nest box, grooming each other, resting in physical contact). After ♀ gave birth, ♂ continued to share the nest box and showed strong parental behaviour towards young when they emerged. Female showed no aggression towards ♂ at parturition or any other time (L. Emmons, unpubl.). These behaviours suggest that these squirrels live in monogamous pairs.

Vocalizations are described in detail in Emmons (1978). The single type of alarm call is a loud buzz composed of about 25 pulses emitted in a one-second burst; pulses are so close together that they are indistinguishable to the human ear. Calls are emitted singly, but can be repeated more than 100 times. The alarm call is always associated with a highly stereotyped visual display in which the squirrel sits, stands, or moves along a branch with the tail held out stiffly behind, its tip curved upward. While it emits a call, the squirrel freezes, then immediately jerks the tail sharply upward until its base is nearly vertical, maintaining a stiff C-shape. As the tail goes up, the hindfeet alone, or both fore- and hindfeet, are hopped or stamped, often moving the body slightly forward. The tail then relaxes to the horizontal and the display may be repeated (see also *Heliosciurus rufobrachium*).

Reproduction and Population Structure Litter-size: 1–2, with more litters of one than of two (Emmons 1979a).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

***Paraxerus vexillarius* SWYNNERTON'S BUSH SQUIRREL**

Fr. Écureuil de brousse de Kershaw; Ger. Lushoto-Buschhörnchen

Paraxerus vexillarius (Kershaw, 1923). Ann. Mag. Nat. Hist., ser. 9, 11: 591. Lushoto, Wilhelmsthal, Usambara, Tanzania.

Taxonomy Originally described in the genus *Funisciurus*. It is possible that the two forms, *vexillarius* and *byatti*, given here as subspecies, are valid species (e.g. as in Allen 1939 and Ellerman 1940). Amtmann (1975) regarded them as forms of *P. vexillarius* and also commented that they may be distinct species. Inexplicably, Kingdon (1974) treated *P. byatti* as a subspecies of *P. lucifer*. See Allen and Loveridge (1933). Synonyms: *byatti*, *laetus*. Subspecies: two. Chromosome number: not known.

Description Large squirrel with grizzled brownish dorsal pelage and sometimes with rufous-orange tip to tail. Dorsal pelage olive-green to brown, grizzled. Ventral pelage dove-grey. Limbs and feet rufous-orange. Tail long (ca. 85% of HB), brown and whitish rings at base, bright orange at tip; hairs at base banded black and white. Skull: cheekteeth $5/4$; posterior end of bony palate in line with posterior end of M^3 ; masseteric tubercle not prominent. Nipples: not known.

Geographic Variation

P. v. byatti: Mt Kilimanjaro, Tanzania. Very similar to *P. v. vexillarius*, but described as being more ochraceous-buff on the back and darker ventrally. This name is usually attributed to animals throughout the range of *P. vexillarius* lacking an orange tail tip, a condition found only among some individuals of the Usambara population, as suggested in the original description of *P. vexillarius*. Perhaps this subspecies should not be recognized.

P. v. vexillarius: Usambara, Uluguru and Uzungwa Mts, Tanzania. Dorsal pelage grizzled brown, greyer on the sides, and dull rufous on the flanks and outside of thighs; arms and shoulders dark rufous, fore- and hindfeet tawny-ochraceous. Tail coloured like back for proximal one-fifth of its length; distally more buff; hairs sometimes tipped more white. Rufous on nose, around mouth, and a broad streak running through the eye to the ear. This name is

Paraxerus vexillarius

usually attributed only to animals with an orange tail tip, but this is probably a local variation within the Usambara population of *P. vexillarius*, as noted by Kershaw (1923).

Similar Species

P. palliatus. Rufous or orange ventral pelage; more widespread distribution.

P. lucifer. Predominantly rufous with black dorsal patch; limited distribution in S Tanzania and N Malawi.

Paraxerus spp., pelage colours. Left to right: *P. cooperi*, *P. lucifer*, *P. palliatus*, *P. poensis* and *P. vexillarius*.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Mountains of NE to S Tanzania (details as above).

Habitat Montane forest.

Abundance No information.

Remarks Arboreal. Feeds on fruits and seeds.

Conservation IUCN Category: Near Threatened.

Survival of this species is threatened because the montane forests of the Usambara Mts are being fragmented and are decreasing in area as a result of expanding agriculture.

Paraxerus vincenti VINCENT'S BUSH SQUIRREL (SELINDA MOUNTAIN SQUIRREL)

Fr. Écureuil de brousse de Vincent; Ger. Vincents Buschhörnchen

Paraxerus vincenti Hayman, 1950. Ann. Mag. Nat. Hist., ser. 12, 3: 263. Namuli Mountain, Mozambique. 5000 ft (= 1500 m).

Taxonomy Classified as a subspecies of *Paraxerus palliatus* by Kingdon (1994, 1997), but considered here to be a valid species because of its very limited distribution and its isolation from all subspecies of *P. palliatus*. *Paraxerus vincenti* is closely related to three other species, *P. lucifer*, *P. palliatus* and *P. vexillarius*. Synonyms: none. Chromosome number: not known.

Description Medium-sized squirrel very similar to *Paraxerus palliatus ornatus*. Dorsal pelage blackish, grizzled. Ventral pelage rich rufous. Crown of head and cheeks darkish-brown, rufous around eye and nasal region. Fore- and hindlimbs and upper surfaces of feet similar to dorsal pelage. Tail long (ca. 100% of HB), blackish-brown tipped with rufous; hairs black at base, rufous at tip. Skull: cheekteeth ⁵/₄; posterior end of bony palate in line with posterior end of M³; masseteric tubercle not prominent. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Paraxerus spp. Ventral pelage less intense and less bright. Hayman (1950) noted that *P. palliatus* has 'brick-red' ventral pelage whereas in *P. vincenti* is rich rufous.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Namuli Mountain, N Mozambique (15°21' S, 37°04' E).

Habitat Moist evergreen forests (Viljoen 1989).

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

GENUS *Protoxerus* Forest Giant Squirrel

Protoxerus Forsyth Major, 1893. Proc. Zool. Soc. Lond. 1893: 189. Type species: *Sciurus stangeri* Waterhouse, 1842.

Monotypic genus. A very large tree squirrel with a wide distribution in the Rainforest BZ and some adjacent rainforest relicts in the Rainforest–Savanna Mosaics. The single species *Protoxerus stangeri* lives in the upper storeys of rainforest, feeds primarily on nuts and fruits, and tends to be solitary.

The genus is characterized by very large size (HB 270–306 mm) and long tail, about the same length as the head and body. The pelage is longer and denser than in *Heliosciurus* spp., and the hairs have three or five bands, which result in a strongly speckled effect. Flanks without longitudinal stripes. The ventral surface is mostly hairless. The tail is long and bushy, and about as long as HB; each hair with 7–9 bands and white at the tip on the dorsal and lateral sides. Females have four pairs of nipples (as in *Epixerus*); ♂♂ have large baculum. The skull is characterized by large size (66–73 mm in length) and is larger than in any other African squirrel; four upper cheekteeth; supraorbital notch closed on margin of orbit forming a foramen piercing the frontal bone; posterior end of bony palate in line with posterior end of M^3 ; anterodorsal process of premaxilla rises to abut evenly with anterolateral angle of nasal; pronounced masseteric ridge; and masseteric tubercle absent or very small (Figure 15).

Protoxerus forms a monophyletic clade with *Heliosciurus*, *Allosciurus* and *Epixerus* (Moore 1959). *Protoxerus* resembles the related genera *Heliosciurus*, *Allosciurus* and *Epixerus* in relative length of tail; differs from *Heliosciurus* but agrees with *Epixerus* in having a small masseteric tubercle (absent in some individuals) and four pairs of nipples. *Protoxerus* also resembles *Epixerus* in speckled pelage of upperparts, contrasting sparse pelage of underparts and banded pattern of tail.

Some authors have allocated *Allosciurus* to *Protoxerus* as a synonym or subgenus (Moore 1959, Amtmann 1966, Thorington & Hoffman 2005), though in many features, *Protoxerus stangeri* is more similar to *Epixerus* than to *Allosciurus*. *Protoxerus* and *Allosciurus* have not been recorded to share derived character-states absent in other squirrels, so are not demonstrably sister-taxa. *Epixerus ebii* has sometimes been misidentified as *Protoxerus stangeri* but their skulls have been compared in considerable detail, and can be readily distinguished. For differences between *Protoxerus* and *Allosciurus*, see *Allosciurus* genus profile.

Peter Grubb

Protoxerus stangeri.

***Protoxerus stangeri* FOREST GIANT SQUIRREL (AFRICAN GIANT SQUIRREL)**

Fr. Écureuil géant de Stanger; Ger. Afrikanisches Riesenhörnchen

Protoxerus stangeri (Waterhouse, 1842). Proc. Zool. Soc. Lond. 1842: 127 (publ. 1943). Fernando Poo (= Bioko I., Equatorial Guinea).

Taxonomy Originally described in the genus *Sciurus*. This species shows considerable geographic variation, which has resulted in 19 named forms; 11 of these may be considered as subspecies (Amtmann 1975, Thorington & Hoffman 2005), although the validity of these subspecies is uncertain. Synonyms: *bea*, *calliurus*, *caniceps*, *centricola*, *cooperi*, *dissonus*, *eborivorus*, *kabobo*, *kwango*, *loandae*, *moerens*, *nigeriae*, *nordhoffi*, *notabilis*, *personatus*, *signatus*, *subalbidus*, *temmincki*, *torrentium*. Subspecies: 11. Chromosome number: not known.

Description Very large long-bodied squirrel with very long ringed tail; the largest African arboreal squirrel. Pelage short and stiff. Dorsal pelage medium brown, grizzled with yellow or buff; hairs banded, black at base, yellow or buff on terminal half, with black tip; some hairs have five alternating dark-pale bands. Ventral surface naked yellow skin; almost hairless. Head large and rounded with conspicuously large cheek muscles. Crown and nasal region of head similar to back except terminal half of hairs are white, giving a frosted appearance to the head. Cheeks thinly haired showing yellow skin below and behind eye; ears short, nearly naked, yellowish. Chest usually white. Limbs and feet short and robust. Tail long (ca. 100% of HB), extremely bushy, mostly black and white; hairs long with 7–9 bands of black and white, with white tips, which result in pale (but sometimes obscure) rings along the length of the tail; undersurface of tail varied, black and white, but not always forming rings. Tail carried straight out behind the body during locomotion, and hangs below body while squirrel is at rest; not normally curled against back. Skull and mandible large and heavily built; cheekteeth $4/4$; posterior end of bony palate in line with posterior end of M^3 ; supraorbital ridge with small foramen; pronounced masseteric ridge; masseteric tubercle inconspicuous or absent. Females slightly larger, on average, than males. Nipples: 1 + 1 + 1 + 1 = 8.

Geographic Variation Amtmann (1975) lists 11 subspecies, as follows, without comment:

- P. s. bea*: Kakamega Forest, Kenya.
- P. s. centricola*: between Congo and Oubangui rivers, DR Congo; forest relics in Uganda; Mt Kungwe, Tanzania; Equatoria District, S Sudan.
- P. s. eborivorus*: E Nigeria south to Ogooué R., Gabon, and east to Oubangui R., DR Congo.
- P. s. kabobo*: Montane forests of Mt Kabobo, E DR Congo.
- P. s. kwango*: near Kasonga Lunda, Bandundu Province, SW DR Congo.
- P. s. loandae*: N Angola.
- P. s. nigeriae*: between Volta R., Ghana and Niger R., Nigeria.
- P. s. personatus*: between Ogooué R., Gabon and Congo R., DR Congo.
- P. s. signatus*: between Congo R. and Kasai R., DR Congo.
- P. s. stangeri*: Bioko I.
- P. s. temmincki*: Sierra Leone to Volta R., Ghana.

*Protoxerus stangeri***Similar Species**

Epixerus ebii. Reddish head, slender body, long legs; ventral surface with yellow skin; mostly terrestrial.

Heliosciurus spp. Smaller, crown the same colour as back, tail slender, ventral surface well haired, without visible yellow skin; arboreal.

Distribution Endemic to Africa. Widely distributed in the Rainforest BZ and Rainforest–Savanna Mosaics from Sierra Leone to the Kavirondoro district of Kenya, and from N Angola to N Tanzania. Recorded from N Angola, Cameroon, Central African Republic, Congo, Côte d'Ivoire, Equatorial Guinea (Rio Muni and Bioko I.), Gabon, Ghana, W Kenya, Liberia, Nigeria, Sierra Leone, N Tanzania, Togo, Uganda and DR Congo.

Habitat Lowland evergreen rainforest and rainforest outliers, mostly at lower altitudes. Within this area, occupies many forest types including tall mature forests, secondary forests, plantations and gardens with trees.

Abundance Common. One of the most abundant and frequently seen species of rainforest squirrels.

Adaptations Diurnal and arboreal, living mostly in the forest canopy and upper vegetation levels (Emmons 1980) but descending to the ground occasionally (J. C. Ray & J. R. Malcolm unpubl.). The short limbs with short, broad palmar and plantar surfaces are suitable for running along large branches and up and down tree trunks

(Emmons 1980). The incisor teeth are robust, and the masseter muscles are massive, as befits its diet of hard nuts (see below). A prominent glandular pocket in the inside corner of the lips may be used in scent marking.

Forest Giant Squirrels nest in tree hollows and favour those with entrances just large enough for the squirrel to squeeze through (mean height 9.3 m; range: 4–17 m; $n = 7$). The nest within the hollow is constructed of twigs with sprays of attached green leaves (Emmons 1975). Animals leave their nests at dawn (range 06:00–06:08h); in Gabon they have a relatively long activity period (mean 10.46 h/day) and return to their nests in the late afternoon or well before dusk (mean entry time 16:33h; range: 15:25–17:55h, $n = 16$; Emmons 1980).

Foraging and Food Primarily vegetarian. In Gabon, feeds mainly on seeds extracted from fruits of trees and lianas, notably from the thick-walled nuts of *Panda oleosa*, *Coula edulis* and species of *Klaineodora*, *Irvingia*, *Elaeis* and many other species. The diet is supplemented by minor amounts of plant vegetative parts (9%) and insects (0.4%) (Emmons 1980). Many of the fruits whose seeds are eaten by Forest Giant Squirrels are primarily dispersed by elephants (Gautier-Hion *et al.* 1980). Ten of 60 observations of feeding in the wild were of insect-hunting behaviour (Emmons 1980), but wild-caught captive Forest Giant Squirrels had little predatory tendency and ignored both live and dead birds, and bird's eggs (Emmons 1975).

Social and Reproductive Behaviour Mostly asocial. Forest Giant Squirrels forage, travel and nest alone; 80% of sightings were of solitary animals, the remainder were either aggressive encounters or mothers followed by young. Individuals appear to avoid each other and can chase conspecifics out of fruiting trees. In captivity, squirrels housed together avoid each other, and there is a complete absence of contact, mutual grooming, chasing, or sharing of nest boxes. Apart from these notes, which suggest a solitary life-style, the social organization is undescribed. An apparent 'mating chase' in which several calling ♂ pursued a presumably oestrous ♀, was seen once by Emmons (1980). Two subadult ♀ (followed by radio tracking) had home-ranges of 3.2 and 5.0 ha (Emmons 1975).

Vocalizations most often heard in the wild are two types of alarm calls: the low intensity alarm consists of repeated soft to loud sniffs or sneezes, sometimes alternating with clicks of the incisors; and the unique, diagnostic, high intensity alarm call is a loud whinny composed

of a mean of 12 modulated pulses that drop in frequency about 300 Hz from beginning to the end of a call, with a mean call duration of 1.3 s. Calls are repeated at intervals of 5–20 s (Emmons 1978). Alarm calls in this species are not accompanied by displays of the tail other than erection of the tail hairs; however, when approaching a strange object, Forest Giant Squirrels may fluff out the tail, raise the base vertically over the back with the tip curled posteriorly downwards, and slowly wave it from side to side (Emmons 1978).

Reproduction and Population Structure There are few records; litter-size seems to be 1–2, with more litters of one than of two (Emmons 1979a). One juvenile (HB 172 mm) in Bwamba, Uganda, in Sep (label, BMNH).

Predators, Parasites and Diseases Preyed upon by eagles and other large raptors. Hunted for its meat where larger game is scarce.

Conservation IUCN Category: Least Concern.

Could be threatened by destruction and fragmentation of rainforest, and by hunting where terrestrial game species are rare.

GENUS *Sciurus*

Squirrels

Sciurus Linnaeus, 1758. Syst. Nat., 10th edn., 1: 63. Type species: *Sciurus vulgaris* Linnaeus, 1758.

The genus contains 28 species widely distributed in North America and South America with a few species in Europe, the Middle East, parts of Asia, and Japan. Since the genus is not indigenous to Africa, and is represented by only one introduced species in a limited area

of South Africa, details of genus are not given (see Thorington & Hoffman 2005 for further details). The single species in Africa is *Sciurus carolinensis*.

Sciurus carolinensis GREY SQUIRREL

Fr. Écureuil Gris; Ger. Grauhörnchen

Sciurus carolinensis Gmelin, 1788. In: Linnaeus, Syst. Nat., 13th edn, 1: 148. Carolina, USA.

Taxonomy This profile refers to the species in Africa only. For general information of the species extraliminally to Africa, see Koprowski (1994), Thorington & Hoffmann (2005) and Southern (1964). Chromosome number: $2n = 40$, $FN = 76$.

Description Very large grey squirrel with bushy tail. Hairs rather coarse. Dorsal pelage yellowish-brown or greyish-brown (summer) to silvery-grey (winter); hairs ca. 10 mm; scattered black guard hairs (ca. 15 mm). Often slightly darker (and/or browner) along mid-dorsal region. Ventral pelage paler, usually grey to greyish-white; hairs less dense; ca. 8 mm. Flanks sometimes with rufous streak at junction of dorsal and ventral pelages. Head similar in colour to dorsal pelage. Ears small, rounded; small white or yellow tuft on each ear tip (winter only). Limbs short but moderately long for a

squirrel; similar in colour to dorsal pelage, sometimes with rufous on upper surfaces; digits with well developed claws. Tail long (ca. 75% of HB), densely covered with long hair (typically 30–40 mm, but up to 45 mm); very large and bushy; yellowish-brown, with subterminal black band and white tip (which gives a ‘frosted’ appearance); tail hairs can be flattened or erected depending on mood. When animal is at rest, tail is held horizontally over back, with the tip pointing vertically upwards. Upper tooththrow with five cheekteeth (the anterior tooth being a very small peg-like P^3 , and sometimes absent) (Figure 16). Albino individuals may occur in some populations (Britain and South Africa). Nipples: $1 + 1 + 1 + 1 = 8$.

Geographic Variation None recorded in Africa.

Similar Species

Heliosciurus rufobrachium. Similar in size; pelage much redder; limbs rufous-red.

Distribution Introduced from North America (via Britain) in ca. 1890–1900 by Cecil Rhodes (at Groote Schuur Estate in Cape Town). Confined to a small area of SW Cape Province, South Africa (in the regions of Cape Town, Stellenbosch, Paarl, Elgin, Swellendam and Ceres). Details of the expansion of Grey Squirrels within South Africa are documented by Davis (1950), Millar (1980) and Lever (1985). Natural expansion of this range is unlikely because of the surrounding unsuitable habitat (e.g. fynbos); currently, the species occurs in suitable patches of habitat within an area of ca. 7000 km², and is confined to urban, agricultural and afforested environments (Long 2003). Extraliminally widespread as an indigenous species in the USA and Canada; introduced into Britain, Ireland and to parts of N Italy; also to parts of Victoria State, Australia (1880–1973, but now extinct) (Lever 1985, Long 2003). Map not given.

Habitat Woodlands with suitable food trees including oaks, selected species of pines, eucalypts, acacias etc. May also occur in fruit orchards if suitable woodlands are nearby. Does not occur in monocultures such as pine plantations, nor in indigenous forests.

Abundance No information; tends to be common in suitable habitats in natural distribution and where introduced successfully.

Figure 16. Skull and mandible of *Sciurus carolinensis* (BMNH 2004.96).

Adaptations Diurnal and arboreal, although may descend to the ground to feed and cross small open spaces. Builds spherical nests (dreys) of twigs, 30–60 cm diameter, amongst branches and twigs of trees; may sometimes live in natural cavities in trees. Activity outside nest varies seasonally and is influenced by temperature. In warmer months with longer days, activity is from after dawn until ca. 10:00h and after 16:00h until near dusk; in cooler months with shorter days, activity is mostly between 10:00h and 14:00h (Millar 1980 in Smithers 1983). In the northern hemisphere, Grey Squirrels enter torpor on cold days and do not leave the drey for several days at a time; whether torpor occurs in South African Grey Squirrels is not recorded.

Foraging and Food Herbivorous, mostly frugivorous. Foods in South Africa include acorns, pine nuts and other deciduous fruits. Occasionally omnivorous; feeding, in addition, on bird's eggs, fungi, pollen, insects, bark and leaves (Millar 1980 in Smithers 1983). The majority of the diet is provided by acorns and pine nuts, which together provide a balanced diet of carbohydrate, protein and fat (acorns: protein 4.9%, fat 5%, carbohydrate 84.5%; pine nuts: protein 31%, fat, 47.4%, carbohydrate 11%) (Millar 1980 in Smithers 1983).

Social and Reproductive Behaviour Usually solitary; may occur in small groups (mother and young). May rest in dreys in small groups (especially in cooler weather). Young are born in the dreys.

Reproduction and Population Structure In South Africa, mating occurs in Jul–Aug and in Nov–Dec; young are born in Aug–Nov (spring) and Dec–Feb (summer). Embryo number: 2.5 (1–4, mode 2 and 3). Litter-size tends to be smaller in spring (mean 2.2, $n = 11$) and

larger in summer (mean 2.6, $n = 16$) (Millar 1980 in Smithers 1983). General information from elsewhere: gestation 44 days; young weaned at ca. Week 7; breeding first occurs in second year of life when 11–16 months of age. Females sometimes have two litters per year.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern (in northern hemisphere).

D. C. D. Happold

GENUS *Xerus*

Ground Squirrels

Xerus Hemprich and Ehrenberg, 1833. Symb. Phys. Mamm., vol. 1, sig. Ee, pl. 9. Type species: *Sciurus (Xerus) brachyotus* Hemprich and Ehrenberg, 1832 (= *Sciurus rutilus* Cretzchmar, 1828).

The genus *Xerus* is endemic to Africa, and comprises four species distributed throughout the semi-arid regions of the continent. Placed in the Tribe Xerini (together with *Atlantoxerus*, the only other genus of ground squirrels). Typical habitats are semi-arid desert, grassland and lightly wooded savannas. Only one species, *Xerus princeps*, inhabits rocky, hilly ground.

The genus is distinguished by its bristly fur and small ear pinnae. Skull characteristics include cheekteeth $5/4$ although upper anterior premolar (P^3) very small and often absent in adults; palate long (ca. 62% of occipital-nasal length) with the posterior end of bony palate well posterior to M^3 (as in *Atlantoxerus* and unlike other sciurids); masseteric tubercle very prominent; lachrymal enlarged; jugal joining the lacrimal with a blunt truncation, supraorbital notch small (occasionally absent), posterior end of bony palate well posterior to M^3 , and masseteric tubercle prominent (Figure 17). Dental formula: $I^{1/1}$, $C^{0/0}$, $P^{2/1}$, $M^{3/3} = 22$ (but see also *Xerus erythropus*). There are two pairs of nipples, although *Xerus erythropus* has three pairs (Moore 1961).

Little is known about the biology and reproduction except for *Xerus inauris*. All four species are diurnal, terrestrial and semi-

Xerus erythropus.

Figure 17. Skull and mandible of *Xerus erythropus* (BMNH 50.21). The first premolar is missing in this specimen.

fossorial. All, except for *X. inauris*, are asocial. Burrows are usually simple, with 2–6 openings. In *Xerus inauris*, groups of ♀♀ maintain complex burrows with multiple burrow openings (up to 60). All four species are mainly herbivorous, feeding on grasses, leaves, fruits and nuts. *Xerus inauris* and *X. rutilus* can breed throughout the year. Litter-size in the genus appears to range from 1 to 6 young/litter.

The genus *Xerus*, together with *Atlantoxerus* and the non-African *Spermophilopsis*, was first placed in the tribe Xerini by Simpson (1945). Nadler & Hoffman (1974) supported the classification of *Xerus rutilus* as a member of the tribe Xerini rather than in a subfamily of its own and subsequently others have supported this classification. The currently recognized species have been described under numerous names, resulting in a long list of synonyms. The genus was split into two subgenera, *Euxerus* and *Geosciurus*, by Simpson (1945). Moore (1959), following Pocock (1923), supported Simpson's classification; however, Moore suggests that *Euxerus* might deserve elevation to generic status. The genus is currently considered to contain three subgenera: *Euxerus* (*X. erythropus*), *Geosciurus* (*X. inauris*, *X. princeps*) and *Xerus* (*X. rutilus*) (Ellerman 1940, Moore 1959, Amtmann 1975, Thorington & Hoffman 2005).

The species are distinguished on the presence or absence of a lateral side-stripe, the number of dark bands on tail hairs, presence or absence of an extra premolar (P^3) in the skull, and the colour of the front incisors.

Jane M. Waterman

***Xerus erythropus* STRIPED GROUND SQUIRREL (AFRICAN GROUND SQUIRREL,
WEST AFRICAN GROUND SQUIRREL, GEOFFREY'S GROUND SQUIRREL)**

Fr. Écureuil fouisseur du Sahel; Ger. Gestreiftes Erdhörnchen

Xerus erythropus (E. Geoffroy, 1803). In: Cat. Mamm. Mus. Hist. Nat., Paris, p. 178. Unknown, but neotype given as Senegal.

Taxonomy Originally described in the genus *Sciurus* and later placed in either the genus *Euxerus* or *Xerus*. *Euxerus* is now considered to be a subgenus by most authors. The species name was first cited as *erythropus* [sic] but the emended spelling is now accepted (see Grubb [2004] for a discussion of the specific name). For general account, see Herron & Waterman (2004). Synonyms: *agadius*, *albovittatus*, *chadensis*, *fulvior*, *lacustris*, *lessoni*, *leucoumbrinus*, *limitaneus*, *maestus*, *marabutis*, *microdon*, *prestigiator*. Subspecies: five. Chromosome number: $2n = 38$ (Dobigny *et al.* 2002b).

Description Large terrestrial squirrel with coarse pelage. Hairs sparse, especially on ventral surface; black skin underlying hairs easily visible. Dorsal pelage dark brown to pale cinnamon and sandy-yellow; hairs sandy coloured at base, sometimes with black or brown tip. Most geographical variation in colour is due to colour of hair tip (see below). Ventral pelage white or pale. Conspicuous white side-stripe on each flank. Head with narrow white stripes above and below the eyes. Ears small and rounded. Limbs and feet paler than dorsal pelage. Tail moderately long (ca. 80% of HB), dorsoventrally flattened, hairs long, with alternating black and white bands; hairs project vertically from tail to form large brush. Males slightly larger than females. Skull: cheekteeth $5/4$ (anterior upper premolar (P^3) may be shed in some

adults so cheekteeth $4/4$); posterior end of bony palate considerably posterior to M^3 ; masseteric tubercle prominent; outer surface of incisor teeth orange. Nipples: $0 + 0 + 1 + 2 = 6$.

Xerus erythropus.

Geographic Variation Many forms of *X. erythropus* have been recognized, all based on differences in pelage colour. Amtmann (1975) and Thorington & Hoffman (2005) recognized six subspecies, and Rosevear (1969) recognized five subspecies. Populations in high to moderate rainfall areas are dark rufous-brown or dark chocolate-brown, those in arid regions are pale oatmeal or sandy; all shades of pelage colour between these extremes are recorded from areas of intermediate rainfall. Six subspecies, of uncertain validity, are listed here.

- X. e. chadensis*: Lake Chad (N Nigeria, W Chad, N Cameroon) and W Sudan. Dorsal pelage buff to creamy-buff. Paler than other subspecies.
- X. e. erythropus*: mainly Sahel Savanna BZ, from Senegal to S Mauritania to NE Nigeria (and perhaps further east). Also SW Morocco. Dorsal pelage pale reddish-brown to sandy-yellow; some hairs on back have black tips.
- X. e. lacustris*: NE DR Congo and Uganda. The darkest brown subspecies. Rosevear (1969) suggests that this subspecies is the same as *X. e. maestus* (see Taxonomy).
- X. e. leucombrinus*: Sudan Savanna BZ from Senegal to Ethiopia, including NW Kenya. Dorsal pelage dark red-brown.
- X. e. limitaneus*: W Sudan. Dorsal pelage similar to *leucombrinus*, darker than *chadensis*. Said to be larger than *leucombrinus* and *chadensis*.
- X. e. microdon*: Rosevear (1969) suggests this subspecies ranges from Senegal to Kenya but Amtmann (1975) suggests it only occurs in SW Kenya. Dorsal pelage dark brown. Rosevear (1969) questions the validity of subspecific status for this form, suggesting that it is the same as *X. e. leucombrinus*.

Similar Species

X. rutilus. Smaller body size; side-stripe absent; lacks the extra premolar characteristic of *X. erythropus* (premolar is often shed in adult *X. erythropus*); marginally sympatric in parts of eastern Africa.

Atlantoxerus getulus. Smaller (HB: 165–230 mm; GLS: 38.4–50.0 mm); pelage soft and less coarse; side-stripe on each flank and single mid-dorsal stripe; usually five upper cheekteeth; sympatric in W Morocco, but more widespread in N Africa, including montane habitats, than *X. erythropus*.

Distribution Endemic to Africa. Widespread across sub-Saharan Africa in Sahel, Sudan and Guinea Savanna BZs, and Northern and Eastern Rainforest–Savanna Mosaics, from Senegal and Mauritania to E Sudan. Extends southwards into margins of Rainforest BZ where there is suitable habitat (see below). Small isolated population in W Morocco (near Agadir). Recorded from SW Morocco, S Mauritania, Senegal, Gambia, Guinea-Bissau, Guinea, Sierra Leone, Côte d'Ivoire, S Mali, Burkina, Ghana, Togo, Benin, SE Niger, Nigeria, N Cameroon, NE Congo, S Chad, Central African Republic, Sudan, NE DR Congo, Uganda, Rwanda, Eritrea, W Ethiopia (except montane regions) and W Kenya. Unconfirmed record in N Tanzania.

Habitat Open habitats in semi-desert, grassland savannas, woodland savannas and coastal scrub, and also in grassy clearings in the Rainforest–Savanna mosaic and the northern edge of the Rainforest BZ. Lives in rocky areas, tree root crevices, termite mounds and self-dug burrows.

Abundance Common. Densities not known.

Adaptations Diurnal and terrestrial. Burrows consist of a central chamber and about three entrance tunnels, and are simpler than those of *X. inauris*. During the heat of the day, Striped Ground Squirrels move into areas of shade or shelter in their burrows. They also press the ventral surface of the body on shaded or cool sand as a means of losing body heat (Ewer 1966, Linn & Key 1996).

Foraging and Food Herbivorous. Feeds mainly on leaves, flowers, roots, seeds, soft fruits, and nuts. The diet may also include insects (especially termites) and meat (Ewer 1966). Food in much of the habitat is patchy and unpredictable, and hence individuals tend to forage alone. Striped Ground Squirrels are scatter hoarders, burying food well away from the burrow entrances (Ewer 1966, 1968). In some regions they are regarded as a pest because of their consumption of maize (Key 1990).

Social and Reproductive Behaviour Asocial. Adults usually live singly or in small family groups. Interactions between individuals are usually brief – two individuals approach and touch nasal areas and then move on. Overt aggression is rare. Often during a meeting, one individual is submissive and the other dominant, but detailed information on these interactions is lacking (Linn & Key 1996).

In an area of periodic drought, when resources were very patchy, home-range size of three ♀♀ averaged 12.4 ha. In an area of higher rainfall, home-range of a single ♀ was 3.34 ha and for four ♂♂ was 9.43 ha. Individuals forage widely within the home-range and often do not return to the same sleeping burrow each night. Home-ranges overlap considerably between conspecifics and there is no evidence of territoriality. Very tolerant of conspecifics and even burrows are not defended from visitations by a succession of other individuals (Linn & Key 1996).

Nothing is known about mating behaviour, although mating chases have been noted (Linn & Key 1996). Young animals participate in

social play but this decreases as they reach maturity. Vocalizations are rare. Juveniles emit distress calls and individuals will give alarm calls while running toward the burrow if they are threatened. Scent marking by rubbing cheek glands on objects has been described as more common in ♀♀ than ♂♂ (Ewer 1966, 1968).

This species appears to be displacing *X. rutilus* in parts of Kenya, possibly because it is more aggressive and larger (Key 1990); however, O'Shea (1976) reported that the two species share burrows.

Reproduction and Population Structure Almost nothing is known about reproduction and growth. Probably breeds prior to one year of age (Ewer 1966). Litter-size: usually 4 (2–5). Eyes open ca. Day 26. First moult ca. Day 55. Eat solid food ca. Week 5 (Ewer 1966). May live up to six years in captivity (Kingdon 1974).

Predators, Parasites and Diseases Major predators include hawks, eagles, snakes (especially Puff Adder *Bitis arietans*), servals, wild cats and jackals (Kingdon 1974). Can harbour a number of diseases, including *Streptobacillus moniliformis*, which causes rat-bite fever (Linn & Key 1996), *Trypanosoma (Herpetosoma) xeri* (Marinkelle & Abdalla 1978) and many species of ticks.

Conservation IUCN Category: Least Concern.

Unlikely to be threatened because of widespread distribution and commonness.

Measurements

Xerus erythropus

Jane M. Waterman

Xerus inauris CAPE GROUND SQUIRREL (SOUTH AFRICAN GROUND SQUIRREL)

Fr. Écureuil fousseur du Cap; Ger. Kaperdhörnchen

Xerus inauris (Zimmermann, 1780). Geogr. Gesch. Mensch. Vierf. Thiere 2: 344. 160 km north of Cape of Good Hope, South Africa.

Taxonomy Originally described in the genus *Sciurus*. Previously allocated to the genera *Sciurus*, *Myoxus*, *Geosciurus* and *Xerus*. Subgenus *Geosciurus*. *Xerus inauris* is considered to be a separate species from *X. princeps* based on minor chromosomal differences and morphological studies (Robinson *et al.* 1986, Herzig-Straschil *et al.* 1991). For a general account, see Skurski & Waterman (2005). Synonyms: *africanus*, *albovittatus*, *capensis*, *dschinshicus*, *gininianus*, *levaillantii*, *namaquensis*, *setosus*. Subspecies: none. Chromosome number: 2n = 38 (Robinson *et al.* 1986).

Description Large terrestrial squirrel with white side-stripes and very small ears (hence the name *inauris*). Hairs sparse and short; dark skin underlying hairs easily visible. Dorsal pelage pale cinnamon-brown; hairs sandy with small white tip; some longer hairs with black tip. Conspicuous white side-stripe from shoulders to hips. Ventral pelage off-white or pale yellowish-white. Eyes large, with dull white stripe above and below each eye, extending anteriorly to nostrils. Testes on ♂♂ large, approximately 19.8% of HB. Forelimbs short, sandy above, off-white below; forefoot with four digits, each with long dark claw. Hindlimbs sandy; hindfoot off-white above, naked below; five digits, each with long dark claw. Tail moderately long (ca. 85% of HB), dorsoventrally flattened; hairs long (ca. 50–60 mm), banded, each hair white with two black bands (short blackish-brown band near base, long black band near tip) and long white tip. Skull: cheekteeth ⁵/₄; posterior end of bony palate considerably posterior

to M³; masseteric tubercle prominent; outer surface of incisor teeth white. Nipples: 0 + 0 + 1 + 1 = 4.

Geographic Variation None recorded.

Similar Species

X. princeps. Incisor teeth orange; tail hairs white with three black bands; tail comparatively longer; marginally sympatric in W Namibia.

Distribution Endemic to Africa. Widespread in semi-arid regions of southern Africa. South-West Arid BZ (Kalahari Desert, Namib Desert and Karoo) and western part of Highveld BZ. Recorded from C South Africa, Botswana, W Lesotho and Namibia. Not recorded from coastal Namibia.

Habitat Open semi-arid regions where mean annual rainfall is 125–500 mm. Preferred habitat is hard ground with some scrub cover along the edges of pans, river beds and open sandy veld; also recorded from short grasslands, overgrazed areas and cultivated fields. In Namibia, areas with short annual grass (*Schmidtia kalahariensis*) are preferred, and areas with longer perennial grasses are avoided.

Abundance Common. In the Kalahari region of SE Namibia, density is 3–4/ha, with approximately 1.2 adult ♀♀/ha, 1.3 adult ♂♂/ha and 1.3 subadults/ha (Waterman 1995). In drought years,

*Xerus inauris*.

density declines significantly (Waterman & Fenton 2000). Probably live in higher densities in areas with higher rainfall, but no comparable data available.

Adaptations Diurnal and terrestrial. Cape Ground Squirrels dig their own complex burrows, which may be 60–80 cm deep, with 60 or more burrow openings within a cluster of burrows and more than one nest chamber in a burrow system (Herzig-Straschil 1978). When digging, the nostrils can be closed. During the heat of the day, the tail is orientated towards the direction of the sun while held up over the body, providing shade on the back and head. Cape Ground Squirrels also use their burrows as thermal retreats (Bennett *et al.* 1984). Their kidneys have a thick medulla, and urine concentrations are high. Hence squirrels can survive largely on metabolic water, without the need for free drinking water (Marsh *et al.* 1978).

Foraging and Food Primarily herbivorous, also omnivorous. The diet consists of leaves, sheaths and roots of grasses, as well as seeds, fruit and insects. Preferred foods in central South Africa include the grasses *Cynodon dactylon* and *Enneapogon brachystachyus*, while in SC Namibia and the Kalahari National Park their diet includes the grasses *Schmidtia kalahariensis* and *Eragrostis lehmanniana* (Herzig-Straschil 1978, Knight 1991, Waterman 1996). They will also feed on the berries of *Boscia albitrunca*, *Grewia flava* and the fruits of *Citrullus lanatus*. Insects consumed include termites, beetles, locusts and caterpillars. No evidence of food hoarding has been found when the contents of burrows were examined. They have been blamed for damage to maize crops in southern Africa, but Zumpt (1970) attributed the damage by squirrels as only 0.2–0.4%.

Social and Reproductive Behaviour Social. Females live in matrilineal groups of 1–4 adult ♀♀ and up to nine subadults of either sex (Herzig-Straschil 1978, Waterman 1995). Colonies can be as large as 30 individuals (Smithers 1971) and several groups of ♀♀

*Xerus inauris*

may inhabit a colony or cluster of burrows (Herzig-Straschil 1978). In Namibia, only a single group of ♀♀ inhabits a burrow area. Some studies have indicated that a dominance hierarchy exists amongst ♀♀ (Herzig-Straschil 1978, Knight 1991), but no such hierarchy was observed in a study in Namibia (Waterman 1995). Adult ♂♂ form permanent, non-aggressive groups of up to 19 individuals that live independently of groups of ♀♀ (Waterman 1995, 1997). On a daily basis, ♂♂ form temporary subgroups (4–5 individuals), the size and individual composition of which are constantly changing. While in these subgroups, ♂♂ forage, sleep and roam their home-range together.

Interactions between members of the same group of ♀♀ are primarily amicable, with frequent approaching, greeting and allogrooming. Agonistic interactions within a group are rare (Herzig-Straschil 1978, Waterman 1996). Juveniles interact as amicably with other members of the group as they do with their mothers. Interactions between different groups of ♀♀ are rare and usually agonistic. Agonistic interactions amongst ♂♂ in an all-male groups are also rare, and injury has never been observed. There is a linear dominance hierarchy in the group, which is correlated with age (Waterman 1995, 1997) and determined by non-aggressive displacements, rather than fighting. Interactions between different groups of ♂♂ have not been recorded.

Females in the same social group share sleeping burrows and home-ranges. Home-range area during a normal rainfall year was 4 ha; however during drought, ranges more than doubled in area (Waterman 1995, Waterman & Fenton 2000). There is some overlap of home-ranges of adjacent female social groups but no overlap of core areas between social groups. Females will defend core areas from neighbouring groups of ♀♀ (Herzig-Straschil 1978). Home-ranges of male groups encompass a number of female groups but are not defended against other male groups, and new ♂♂ are accepted into the band without aggression (Waterman 1995). Males forage and roam their home-range together in smaller subgroups, sleeping

together in vacant burrow clusters away from groups of ♀♀, and may join and leave a subgroup on a daily basis, resulting in continuous fission and fusion of subgroups (Waterman 1995, 1997). Average range size of radio-collared ♂♂ was 12.5 ha (Waterman 1995). Herzig-Straschil (1978) found smaller home-ranges for both ♂♂ and ♀♀ in a region with high rainfall. Herzig-Straschil (1978) described single ♂♂ associating with groups of ♀♀ for a few weeks during receptivity. Observations in Namibia and central South Africa suggest members of male subgroups travel together from one female group to another. Male subgroups sleep or stay in an occupied burrow area if a ♀ is coming into oestrus, otherwise they sleep in vacant burrow areas (Waterman 1995, 1997, unpubl.). The majority of ♂♂ from the male group will attempt to mate with the ♀ on her day of oestrus.

Oestrus and parturition were asynchronous within and between groups of ♀♀. The operational sex ratio on a day of oestrus (oestrus lasts about 3 h) averaged ten ♂♂ to a ♀. Mating occurs both above and below ground, and the most dominant ♂ usually has preferential access to the oestrous ♀. Both ♂♂ and ♀♀ mate promiscuously. The large size of the testes of ♂♂ suggests that sperm competition could be an important element of their mating system (Waterman 1998).

All members of the group (mother, other adult ♀♀ and subadult ♀♀ and subadult ♂♂) provide care of juveniles through allogrooming, play and possibly predator detection and deterrence (Waterman 1995, unpubl. data). Knight (1991) reported seeing communal nursing. There is no male parental care.

Cape Ground Squirrels have a number of vocalizations, including a high pitched alarm call that is given when the animal detects a potential threat. They will also respond to the alarm calls of other species, particularly Crowned Plovers and White-browed Sparrowweavers. Other vocalizations include an aggressive growl (used in encounters with conspecifics), a scream (used when released from a trap), a play call (used by young animals), nest-chirping (used in infants) and a protest squeak (Herzig-Straschil 1978). Adult ♂♂ and ♀♀ use secretions from the anal-genital region and the circumoral area for marking. Secretions are deposited by rubbing the body on the sand or by rubbing the snout on an object (Straschil 1975). Marking is most common on emergence from the burrow in the morning. Cape Ground Squirrels frequently share their burrow systems with Yellow Mongooses *Cynictis penicillata* and Suricates *Suricata suricatta*. The three species usually ignore each other and rarely interact (J. Waterman unpubl.).

Reproduction and Population Structure Reproduction occurs throughout the year, with peaks of mating in the dry winter months. Litter loss is high, with some 70% of all oestrus cycles failing to produce successful litters (Waterman 1996). Females can have 1–4 litters per year. Gestation: 7 weeks. Litter-size: 1–4. Body weight at 7 days: 23.5 g (Herzig-Straschil 1978). Mothers lactate for

7.5 weeks. Sex ratio of litters at emergence is 1 : 1. Sexual maturity: 8 months (♂), 10 months (♀). Female maturity is delayed within larger groups of ♀♀ (Waterman 2002).

Dispersal is male-biased. Males disperse at 8–10 months of age, whereas ♀♀ usually remain in their natal group. Adult sex ratio is 1 : 1 and the annual survival of ♂♂ is slightly higher than that of ♀♀ (78% vs. 70%). In captivity, individuals may live up to 13 years but the life-span in the wild is most likely to be 4–5 years. Survival of young to six months of age is negatively influenced by the number in the social group (Waterman 2002). During drought, the social structure remains intact; however, densities drop significantly and all reproductive activity ceases (Waterman & Fenton 2000).

Predators, Parasites and Diseases Major predators include hawks, eagles, snakes, wild cats and jackals. Individuals of a group may mob potential predators such as Cape Cobras *Naja nivea*, Puff Adders *Bitis arietans* and Monitor Lizards *Varanus exanthematicus* (Waterman 1996, unpubl.). Ectoparasites include many species of fleas, ticks and mites (De Graaff 1981). Endoparasites include various helminth worms. Some of these parasites are vectors of human diseases such as plague, enterobiasis, biliary fever, East Coast fever and tick-bite fever (De Graaff 1981 and references therein).

Conservation IUCN Category: Least Concern.

***Xerus princeps* DAMARA GROUND SQUIRREL (MOUNTAIN GROUND SQUIRREL, KAOKOVELD GROUND SQUIRREL)**

Fr. Écureuil fouisseur du Damara; Ger. Damara-Erdhörnchen

Xerus princeps (Thomas, 1929). Proc. Zool. Soc., Lond. 1929: 106. Otjitundua, central Kaokoveld, N Namibia.*Xerus princeps*.

Taxonomy Originally described in the genus *Geosciurus*. Minor chromosomal and morphological differences of the skull support *Xerus princeps* as a separate species from *X. inauris* (Robinson *et al.* 1986, Herzig-Straschil *et al.* 1991). For general account, see Waterman & Herron (2004). Synonyms: none. Chromosome number: $2n = 38$ (Robinson *et al.* 1986).

Description Large terrestrial squirrel similar in appearance to *X. inauris*. Hairs sparse, coarse and short; dark skin underlying hairs easily visible. Dorsal pelage cinnamon-brown flecked with white; hairs sandy or dark brown at base, white at tip, which gives the species a more 'grizzled' appearance than *X. inauris*. Conspicuous white side-stripe from shoulders to hips. Ventral pelage white. Eyes large, with dull white stripe above and below each eye extending anteriorly to nostrils. Ears small. Tail long (ca. 99% of HB), dorsoventrally flattened; hairs long (ca. 70 mm), banded, each hair white with three black bands (two short blackish-brown bands near base, long black band near tip) and long white tip. Skull: cheekteeth $5/4$; posterior end of bony palate considerably posterior to M^3 ; masseteric tubercle prominent; outer surface of incisor teeth white or pale orange. Nipples: $0 + 0 + 1 + 1 = 4$.

Geographic Variation None recorded.

Similar Species

X. inauris. Incisor teeth white; tail hairs white with two black bands; tail comparatively shorter; distribution more extensive; very social.

Distribution Endemic to Africa. South-West Arid BZ, mainly in the Namib Desert. Recorded from only the narrow band of the western escarpment that runs from SW Namibia north to SW Angola.

Habitat Rocky, hilly ground in arid areas where mean annual rainfall is ca. 125–250 mm (Herzig-Straschil & Herzig 1989). Also recorded on open plains, but prefers habitats with gravel and rocks in areas with single trees or sparse bush cover.

*Xerus princeps*

Abundance Herzig-Straschil & Herzig (1989) suggest that densities are very low. No detailed information.

Adaptations Diurnal and mainly terrestrial. Burrow systems are simple when compared to *X. inauris*, with only 2–5 openings and a single nest chamber (Herzig-Straschil & Herzig 1989). Burrow entrances are usually found under piles of rocks or boulders. Damara Ground Squirrels use the tail as a thermal shade (as described for *X. inauris*) and they are better adapted to survive high temperatures than *X. inauris* (Haim *et al.* 1987). The thermoneutral zone of *X. princeps* is 32–35 °C, and hyperthermy occurs at 35 °C (Haim *et al.* 1987). Salivation was observed at 38 °C. Thermal conductance was high (0.084 ± 0.005 ml O_2 /g/h/ °C), which results in high heat dissipation and water conservation. In comparison with *X. inauris*, the faeces of *X. princeps* are significantly drier ($14.21 \pm 4.2\%$ moisture content) (Haim *et al.* 1987).

Foraging and Food Mainly herbivorous. Feeds on the base of grass stems and roots. In mopane savanna, animals have been observed climbing mopane trees (*Colophospermum mopane*) to feed on plant lice (*Copaijera mopane*) and on mopane leaves (Herzig-Straschil & Herzig 1989).

Social and Reproductive Behaviour Solitary, or small family groups (mother and young) of 2–4 individuals (Haim *et al.* 1987, Herzig-Straschil & Herzig 1989). Adult ♂♂ are associated with some groups but otherwise live solitarily. No allogrooming, playing or other

cohesive behaviours have been documented during the short period of time they have been observed (Herzig-Straschil & Herzig 1989).

Reproduction and Population Structure Little information. Breeding most likely occurs during the winter months. Gestation: ca. 7 weeks. Litter-size: 1–3 (Herzig-Straschil & Herzig 1989).

Predators, Parasites and Diseases Nothing is known about potential predators. The only recorded ectoparasite is a flea (*Ctnocephalides connatus*) (De Graaff 1981).

Conservation IUCN Category: Least Concern.

The limited geographical range and comparative rarity of the species may be cause for concern in the future (Waterman & Herron 2004).

Xerus rutilus UNSTRIPED GROUND SQUIRREL (PALLID GROUND SQUIRREL)

Fr. Écureuil fousseur unicolore; Ger. Streifenloses Erdhörnchen

Xerus rutilus (Cretzschmar, 1828). In: Rüppell's Atlas Reise Nordl. Afr., Zool., Säugeth. p. 59. Eastern slope of Abyssinia, Ethiopia (probably Massawa, Eritrea – see Mertens 1925: 26).

Xerus rutilus.

Taxonomy Originally described in the genus *Sciurus*. Polytypic with up to eight subspecies (Amtmann 1975, O'Shea 1991). For a general account, see O'Shea (1991). Synonyms: *abessinicus*, *brachyotis*, *dabagala*, *dorsalis*, *fuscus*, *intensus*, *massaicus*, *rufifrons*, *saturatus*, *stephanicus*. Subspecies: eight (validity uncertain). Chromosome number: 2n = 38 (Nadler & Hoffmann 1974).

Description Medium-sized terrestrial squirrel with bristly coarse pelage and without side-stripe. Dorsal pelage pale tan to rich reddish-brown with variable amounts of pale and dark speckling; hairs short (ca. 5–6 mm), dark reddish-brown at base, with buff or black tip. Individuals in drier areas tend to be pale. No side-stripe (cf. all other species in genus). Ventral pelage whitish, and paler than dorsal pelage; hairs sparse. Head with conspicuous white or off-white eye-ring. Ear small. Upper surface of fore- and hindfeet white (reddish-brown in some individuals). Tail of moderate length (ca. 86% of HB); hairs long (ca. 40 mm), each hair banded, off-white at base, blackish-brown in middle, with reddish-brown (e.g. Tanzania) or white (e.g. Somalia) at tip. Skull: cheekteeth ⁴/₄; posterior end of bony palate considerably posterior to M³; masseteric tubercle prominent; outer surface of incisor teeth orange. Nipples: 0 + 0 + 1 + 1 = 4.

Geographic Variation The validity of the eight subspecies is dubious (Amtmann 1975). Differences in pelage colouration perhaps only reflect differences in soil colouration rather than taxonomic differences. Populations in drier areas tend to be paler.

X. r. rutilus: N Ethiopia and NE Sudan. Dorsal pelage reddish brown.

X. r. dabagala: Somalia and southern Ethiopia. Dorsal pelage dull to bright rufous or tawny.

X. r. intensus: Gerlogubi Wells; red sandy country of C Somalia. Hairs of crown and dorsal region tipped with white. Tail rufous at base above and white below.

X. r. stephanicus: L. Stephanie, Ethiopia. Dorsal pelage grizzled yellowish-grey.

X. r. rufifrons: Guaso Nyiro, N Kenya. Rufous marking on muzzle extends onto dorsal region of head.

X. r. saturatus: SE Kenya and NE Tanzania. Dorsal pelage with dark reddish tinge.

X. r. dorsalis: L. Baringo, Kenya. Dorsal pelage dark olive, speckled with yellow and white.

X. r. massaicus: Masai Reserve, Kenya. Rufous tinge on forehead, yellow on throat and underparts; skull appears to be larger than in other subspecies.

Similar Species

X. erythropus. Larger body size; side-stripe present; extra premolar (P³) present in some individuals; sympatric in some parts of geographic range.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded in NE Sudan, E and S Ethiopia, Djibouti, Eritrea, Somalia,

Xerus rutilus

Kenya, NE Uganda and NE Tanzania. The geographic range appears to be contracting in some areas of Kenya, possibly as a result of competition with the larger more aggressive *X. erythropus* (Key 1990).

Habitat Semi-arid dense thornbush interspersed with open grassland (O'Shea 1991). In South Turkana, Kenya, lives in alluvial flats and gullies and in thickets of *Salvadora persica* (Coe 1972).

Abundance Common. In South Turkana, Kenya, estimated densities may reach 848 individuals/km² or approximately 8.5 individuals/ha (Coe 1972).

Adaptations Diurnal and terrestrial. Burrows are often located at the base of bush stems or in termite mounds, and usually have 2–6 entrances. Unstriped Ground Squirrels may also shelter in the burrows of other mammals (including *X. erythropus* [O'Shea 1976]). In order to prevent overheating, the ventral surface of the body is pressed onto shaded or cool sand (Coe 1972).

Foraging and Food Herbivorous and omnivorous. Feeds on herbaceous plants including seeds, leaves, flowers, soft fruits and the large fruits of baobab trees, as well as insects (Coe 1972, O'Shea 1991). Greater than 50% of stomach contents were found to be small dry seeds and leaves (Coe 1972). Unstriped Ground Squirrels are scatter-hoarders, storing food in many caches (O'Shea 1976).

Social and Reproductive Behaviour Primarily a solitary species, although small family groups (mother and young), and ♂♂ living with one or two ♀♀ are also common (O'Shea 1976). Numbers of individuals sharing a burrow system can range from 1 to 6 (Coe 1972; O'Shea 1976). Individuals of different sexes tend to avoid each other; however, at feeding sites ♂♂ appeared to be dominant over ♀♀, as indicated by chases and displacements. Threat behaviour

includes lunges by the dominant individual, but biting and fighting have not been observed (O'Shea 1976). A number of vocalizations have been noted, including churring vocalizations used by ♀♀ and juveniles when approached by ♂♂, and a scolding chatter given by dominant individuals to subordinates (O'Shea 1976).

Home-ranges of ♂♂ (7 ha) are larger than those of ♀♀ (1.4 ha); home-ranges overlap considerably within and between the sexes. There is no evidence of territoriality but individuals with overlapping home-ranges appear to form a linear dominance hierarchy.

Males court ♀♀ by pilo-erecting the hairs of the tail, arching the tail over the head and approaching the ♀♀. Females usually move away, making quiet vocalizations, flicking the tail rapidly and slightly dragging the perineal region of the body on the ground. When ♂ approaches ♀, she takes a prostrate posture and rolls onto her side allowing ♂ to sniff her anogenital region. The ♂ then mounts the prostrate ♀ (O'Shea 1976). Young are born in burrows, which are usually located at the edge of a female's home-range. Three to four weeks after the juveniles emerge, ♀ returns to the centre of her home-range, away from the juveniles (O'Shea 1976).

Reproduction and Population Structure Almost nothing is known about reproduction and population dynamics. Breeding appears to occur throughout the year. Litter-size: one or two (Kingdon 1974, O'Shea 1991). All young eventually disperse from their natal area (O'Shea 1976). Sex ratio is probably 1 : 1 (Coe 1972). In captivity, a single ♂ has been documented to live for over six years (O'Shea 1991).

Predators, Parasites and Diseases No information on potential predators. Ectoparasites include a tick that is specific to the species (*Haemaphysalis calarata*), and a flea (*Synosternus somalicus*). One cestode (*Catenotaenia geosciuri*) also recorded (O'Shea 1991).

Conservation IUCN Category: Least Concern.

The species does not appear to be threatened at the present time.

Family GLIRIDAE

DORMICE

Gliridae Muirhead, 1819. Glirini Muirhead, 1819: 433. Mazology [sic]. pp. 393–480, pls. 353–358, in *Edinburgh Encyclopedia*, Vol. 13 (D. Brewster, ed.).

| | | |
|--------------------------------|----------------|--------|
| <i>Eliomys</i> (2 species) | Garden Dormice | p. 104 |
| <i>Graphiurus</i> (14 species) | Dormice | p. 109 |

The nine genera and 28 living species of Gliridae (commonly known as dormice) are currently arranged in three subfamilies and occur in tropical and temperate forests, savannas, steppes and deserts in Africa and the Palaearctic region (Holden 2005). The name Myoxidae is the original name for this family, but the Commission on Zoological Nomenclature (see Holden 2005) has ruled that the name is invalid, and that Gliridae is the valid family name for dormice. The family is divided into three subfamilies: Glirinae, Leithiinae and Graphiurinae (Wahlert *et al.* 1993, Montgelard *et al.* 2003, Holden 2005). The Glirinae contain *Glis*, indigenous to Europe, N Turkey, Caucasus, N Iran and SW Turkestan; and *Glirulus*, endemic to the Japanese islands of Honshu, Dōgo, Shikoku and Kyushu. The Leithiinae contains the genera *Chaetocauda*, *Dryomys*, *Eliomys*, *Muscardinus*, *Myomimus* and *Selevinia*, and is distributed throughout Europe, the Middle East, C and W Asia; the geographic range of *Eliomys* also includes North Africa. The subfamily Graphiurinae contains only *Graphiurus*, and is endemic to sub-Saharan Africa. The family is represented in Africa by *Eliomys* (2 spp.) and *Graphiurus* (14 spp.).

Living glirids range in body size from small to moderately large (HB 60–190 mm) although the maximum HB for nine of the 16 African glirid species is ca. 100 mm. The tail (40–165 mm) is usually moderately long relative to body size, and well-covered with hair throughout its length (in a similar way to the tail of squirrels). Most species have thick, soft dorsal pelage, are predominantly arboreal and resemble small squirrels in body form. Two exceptions are

the non-African *Myomimus* and *Selevinia*, which are terrestrial and have thinly haired tails. Colour of dorsal pelage ranges from pale grey to dark brown. Many species have a narrow or broad dark stripe (eye-mask) extending from the muzzle to the ears; some species exhibit only a thin dark line (eye-ring) encircling the eyes. Colour of ventral pelage is usually grey or white. In several species, especially in *Graphiurus* and the non-African *Glis*, the chin, chest and sometimes forelimbs are discoloured in many individuals; this discolouration is often reddish-brown, but is sometimes pale yellow or yellowish-green (Channing 1984, Nowak 1999, M. E. Holden unpubl.). This discolouration may result from staining that occurs when the dormice ingest insects (such as earwigs) and certain fruits (Chapin [in Hatt 1940a], Rosevear 1969, Nowak 1999), or it may be genetically induced (Channing 1984, B. Kryštufek & R. M. Baxter pers. comm.). All species have rounded ears, large eyes and short fore- and hindlimbs. The forefeet have four digits, the hindfeet have five and the palmar and plantar surfaces are naked. Claws are short and sharp, and those of arboreal species are recurved. The skull is smooth, usually without postorbital processes or supraorbital and temporal ridging. The zygomatic arches are prominent, the anterior palatal foramina are generally short, their posterior margins usually anterior to or even with the front margins of the ventral maxillary zygomatic processes, and the bony palate is long. Auditory bullae are usually large, often appear inflated relative to skull size and are divided internally by bony septae. The infraorbital foramen is moderately tall, ovate and is penetrated by a portion of the anterior medial masseter. The zygomatic plate, from which originates part of the anterior lateral masseter, tilts upwards in all genera (modified or convergent

Table 14. Species in the family Gliridae. Arranged in order of increasing head and body length. (n. d. = no data.)

^a P⁴–M³

myomorphous configuration) except in *Graphiurus* where it is below the infraorbital foramen (modified hystricomorphous condition, except no separate infraorbital neurovascular foramen is present, which is a feature of true hystricomorphy). The zygomatic plate is narrow, and its anterior margin does not project forward beyond the dorsal maxillary zygomatic process, so no zygomatic notch is present. The mandible has laterally directed angular processes that are usually perforated. Dental formula: $I^{1/1}, C^{0/0}, P^{1/1}, M^{3/3} = 32$. Incisor tips form V-shaped cutting edges (forming a V-shaped notch from anterior view) in most species of *Graphiurus*, but straight cutting edges in species of *Eliomys* and other glirids. Premolars are absent in the non-African *Selevinia*, and markedly reduced in *Graphiurus* *ocularis*. Cheekteeth are low-crowned (brachydont), and their occlusal patterns are variations of four transverse lophs into which cusps are subsumed, forming a range of patterns defined by basins, transverse ridges and accessory crests. Glirids do not have a caecum, and lack a noticeable morphological boundary between large and small intestines. The arterial circulation to the brain is provided by the vertebral artery (the same pattern as in squirrels) rather than the internal carotid (the primitive condition). Females of all glirid species usually have four pairs of nipples (pectoral, brachial, and two inguinal) although some variation has been documented in the non-African *Glis* (Kryštufek 2004). These and other morphological attributes of glirids are described, illustrated and reviewed by Ellerman (1940), Klingener (1984), Bugge (1985), Wahlert *et al.* (1993), Holden (1996), Nowak (1999), Rossolimo *et al.* (2001), Potapova (2001) and Holden (2005).

Glirids are one of the oldest families of living rodents. Their fossils first appear in the early Eocene deposits (Daams & De Bruijn 1995, Daams 1999), suggesting a late Palaeocene-early Eocene origin (Hartenberger 1994, 1998). This is concordant with the most recent molecular dating estimate based upon combined markers (Huchon *et al.* 2002, Adkins *et al.* 2003, Montgelard *et al.* 2003). Most extant glirid genera were clearly differentiated and exhibited their greatest

species diversity by the early to middle Miocene (Hartenberger 1994, Daams & De Bruijn 1995, Daams 1999). The Graphiurinae are an exception; definite examples of *Graphiurus* are known only as far back as the Pliocene (Pocock 1976, Hendey 1981), although late Miocene graphiurines have been recorded from South Africa and Namibia (Denys 1990b, Mein *et al.* 2000b). The living Palearctic genera are relicts of a rich adaptive radiation of up to 15 genera.

Modern glirids (excluding species of *Graphiurus*) have been characterized as myomorphous, and several authors have included Gliridae within the suborder Myomorpha (Simpson 1945, Chaline & Mein 1979, Wahlert *et al.* 1993, McKenna & Bell 1997). Wahlert *et al.* (1993) placed them within Myomorpha based on derived cranial characters; their phylogenetic reconstruction indicated that the hystricomorphous-like *Graphiurus* is the most primitive extant glirid, and the myomorphy exhibited by all other extant glirids is convergent to that of true myomorphs. The terms 'pseudomyomorphy' (Vianey-Liaud 1985, Maier *et al.* 2002) or 'pseudosciuromorphy' (Landry 1999) have been employed to distinguish the zygomaseteric muscular arrangement found in glirids from that of muroids, and Maier *et al.* (2002) noted that pseudomyomorphy (the convergent myomorphous musculature of glirids) is one of the derived diagnostic characters of Gliridae.

The origin of glirids, and the evolutionary relationship between glirids and other rodent groups, are subjects of historical debate and controversy (Holden 2005). Glirids have alternately been placed in the rodent suborder Myomorpha (Simpson 1945, Wahlert *et al.* 1993 and references therein), in the infraorder Sciuirida (that also contains Sciuiridae; see Meng 1990, McKenna & Bell 1997) and in the suborder Sciuromorpha (in subfamily Microparamyinae; Vianey-Liaud 1994, Vianey-Liaud & Jaeger 1996). There is an overwhelming lack of support for inclusion of glirids in Myomorpha based upon recent morphological and molecular research (see Holden 2005, and references therein), and they are currently placed in the suborder Sciuromorpha (Carleton & Musser 2005). Most researchers

currently agree with Wahlert *et al.* (1993) that the myomorphous-like zygomaseteric structure exhibited by most living glirid species is convergent with that of muroids, and most advocate glirid 'pseudomyomorphy' as being derived from a protrogomorphous ancestor.

Vianey-Liaud & Jaeger (1996) proposed that Gliridae are paraphyletic, hypothesizing that graphiurines and anomalurids are closely related and should possibly be placed in the same family because, in their view, both groups are descended from African Eocene zegdomyids. However, results from all other morphological inquiries, as well as molecular information, do not support this hypothesis, but rather support the monophyly of Gliridae (Meng 1990, Wahlert *et al.* 1993, Hartenberger 1994, 1998, Catzefflis *et al.* 1995, Daams & De Bruijn 1995, Hänni *et al.* 1995, Robinson *et al.* 1997, Suzuki *et al.* 1997, Debry & Sagel 2001, Montgelard *et al.* 2002, 2003). Results of molecular analyses by Bentz & Montgelard (1999) and Montgelard *et al.* (2002, 2003) explicitly refute paraphyly and phylogenetic alliance with anomalurids.

Ecological information on African dormice is rather sparse, and only a few species have been studied in a moderate amount of detail. Most species of dormice are primarily arboreal, and three species are mainly found in rocky habitats. The digits of the fore- and hindfeet grip small twigs and branches, and the long claws allow for climbing up slightly uneven surfaces such as rock faces, boulders, tree trunks and walls. Dormice live in many arboreal habitats, such as forests, scrublands, plantations, orchards and woodland savannas where there are suitable hollows and crevices for nesting (see also below). They have been recorded in holes of trees, woodpiles, human houses, thatched rondavels, gardens, kitchens and food stores, banana plantations, date palms, abandoned nests of weaver-birds and beehives. Rock-living species (such as *Eliomys* spp. and *G. ocellaris*) are found on limestone cliffs, in caves, under boulders and in rock crevices. In all these habitats, dormice build spherical nests of vegetation (shredded bark, leaves), which are lined with hair or wool; entrance holes for nests are hard to find, perhaps because it is important that dormice need to be totally surrounded by warm

nesting material to ensure adequate thermoregulation (see below). Dormice do not dig (or live in) burrows and hence are rarely trapped on the ground.

Most studies suggest that dormice are vegetarians or omnivores. Details on the diet vary according to species and location, but there are few detailed studies. Vegetable foods include nuts, seeds, berries, cocoa pods, oil palm nuts, paw-paw, bananas and other fruits. Animal foods include eggs and a wide variety of insects (e.g. grubs, moths and earwigs) and other invertebrates (millipedes). One species (*Eliomys munbyanus*) has been observed catching butterflies.

Dormice are mostly nocturnal, although there are a few records of daytime activity. When active, dormice are agile and swift, running swiftly along twigs and branches and up and over walls and rocks. However, activity is temperature dependent. In cooler weather, dormice become lethargic and torpid (hence the vernacular name 'dormouse' from the Latin *dormire* = to sleep). In those species that have been studied, Tb drops dramatically when Ta is low and/or when food is limited.

Social organizations, and how they may change during the year, are virtually unknown. Most species appear to be solitary except when mothers are with their young, and when a male associates with his mate and young. Some species (e.g. *Graphiurus ocellaris*, *G. platyops*, *G. kelleni*) are known to emit a variety of specific vocalizations and displays, which indicate, for example, agonistic behaviour and non-aggressive communication. Some species (e.g. *G. ocellaris*) may have territories, but nothing is known in this regard for most species. Reproductive behaviour is also poorly known: there are typically 2–3 young (maximum about six); reproduction in the temperate parts of Africa appears to be mainly during summer, but information from tropical Africa is too scanty to make any generalizations.

The two African genera are distinguished by the length of the rostrum, form of the zygomatic plate, zygomaseteric musculature arrangement, relative position of certain cranial foramina, dental morphology and facial colour pattern (Table 14).

Mary Ellen Holden

GENUS *Eliomys*

Garden Dormice

Eliomys Wagner, 1840. Gelehrte Anz. I. K. Bayer. Akad. Wiss., München 8 (37):297. (See Kryštufek & Kraft (1997) for clarification of the publication date for *Eliomys* Wagner [1839 or 1840]). Type species: *Eliomys melanurus* Wagner, 1840.

There are three living species in the genus *Eliomys*: *E. quercinus* is a European endemic that occurs from Western Europe east to the Urals, and on numerous Mediterranean islands; *E. melanurus* is distributed in southern Turkey, the Middle East (Sinai to Iraq) and eastern North Africa; and *E. munbyanus* is endemic to western North Africa (Holden 2005). The habitats of the two African species include desert scrub, rocky escarpments, limestone cliffs and cultivated areas.

The genus is characterized externally by a conspicuous striking facial colour pattern (dark, broad eye-mask that extends posteriorly under ears, and which contrasts with pale (white or cream) cheeks and postauricular patches), and by the contrasting colours of tail and tail tip. The skull is distinguished by a long and narrow rostrum, an upward tilted zygomatic plate in which the anterior margin extends

slightly anteriorly to the infraorbital foramen, pseudomyomorphous (convergent myomorphous) zygomaseteric musculature arrangement, position of certain cranial foramina, the presence of four clearly defined transverse lophs or ridges on cheekteeth, and differences in incisor enamel microstructure (Ellerman 1940, Wahlert *et al.* 1993, von Koenigswald 1993, 1995, Nowak 1999) (Figure 18).

All species of *Eliomys* are predominantly arboreal and partly terrestrial, and are nocturnal. They are agile climbers. The two species in Africa are omnivorous, and consume fruits, seeds, invertebrates and small vertebrates. Individuals of both species become torpid at low ambient temperatures.

The closest living relative of *Eliomys* is probably *Dryomys*, which is distributed in Europe, the Middle East and central Asia. This

Eliomys melanurus.

relationship is supported by cranial and dental characters (Wahlert *et al.* 1993, von Koenigswald 1993, 1995, Daams & De Bruijn 1995, Potapova 2001, Rossolimo *et al.* 2001), and by molecular data (Bentz & Montgelard 1999, Montgelard *et al.* 2003). The evolutionary history of *Eliomys* dates from the middle Miocene of Europe, and from the early Pliocene of western Asia and the Mediterranean region (Daams & De Bruijn 1995, Nadachowski & Daoud 1995). In Africa, it is known only from Pleistocene sediments in North Africa (Mein & Pickford 1992, McKenna & Bell 1997). *Eliomys* possibly reached Africa at least twice, once during the Messinian (6.7–5.2 mya) from Iberia, and later during the late Pleistocene from the eastern Mediterranean. Multiple colonizations may account for the lack of morphometric cohesion among certain populations of North African endemic *E. munbyanus*.

Figure 18. Skull and mandible of *Eliomys melanurus* (RMCA 91-090-M-45).

The two species are distinguished by body size, absolute lengths of ear and tail, degree of conspicuousness of postauricular patches, bushiness of tail, colour of the tail tip and by skull characters. The two species are mostly allopatric, although they are marginally parapatric in Libya.

Mary Ellen Holden

Eliomys melanurus LARGE-EARED GARDEN DORMOUSE

Fr. L  rot du Sud-Est Asiatique; Ger. Gro  hr L  ffelbilch

Eliomys melanurus (Wagner, 1840). Gelehrte Anz. I. K. Bayer. Akad. Wiss., M  nchen 8 (37): 299.

Sinai (restricted to vicinity of Mt Sinai by Nader *et al.* 1983), Egypt.

Taxonomy Originally described in genus *Myoxus*. *Eliomys melanurus* has historically been listed as a synonym of *E. quercinus* (Niethammer 1959, Corbet 1978), but more recently recognized by most researchers as a separate species (Ellerman & Morrison-Scott 1966, Niethammer 1987, Holden 1993, 2005, Filippucci *et al.* 1988b, c, Harrison & Bates 1991, Kry  tufek & Kraft 1997). The geographic distribution and taxonomy of *E. melanurus* remains unresolved (Holden 2005). Based on morphometric analyses, many authors (e.g. Kahmann & Thoms 1981, Niethammer 1987, Kry  tufek & Kraft 1997 and references therein) assign the western North African populations to *E. quercinus*, and the eastern North African and Middle Eastern populations to *E. melanurus*. Filippucci *et al.* (1988b, c), Filippucci & Kotsakis (1995) and Filippucci & Capanna (1996) analysed allozymic and karyological characters and identified all North African and Middle Eastern populations as *E. melanurus*. Holden (2005) agreed with Kry  tufek & Kraft (1997) that only eastern North African and Middle Eastern populations represent *E. melanurus*, but suggested (as

Delibes *et al.* 1980 did) that the western North African populations should be recognized as a separate species, *E. munbyanus*, and that it is probably closely related to *E. melanurus*. Synonyms: *cyrenaicus*. Subspecies: none. Chromosome number $2n = 48$ (Filippucci *et al.* 1988b, c, 1990, Zima *et al.* 1995).

Description Medium-sized dormouse. Dorsal pelage ranges from reddish- and yellowish-brown to yellowish-grey. Pelage soft, sometimes woolly, and moderately long (rump hairs 10–12 mm, guard hairs up to 17 mm). Ventral pelage white or cream slightly suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage; paler towards muzzle. Eyes large; dark eye-mask conspicuous. Cheeks cream or white, forming part of a pale lateral stripe that extends from cheeks to shoulders. Ears large, brown, oval-shaped. White or cream postauricular patches usually present, though sometimes inconspicuous. Hindfeet white. Tail long (ca 95% of HB), hairs

shorter at base (3–4 mm) and longer at tip (up to 23 mm); dorsally black, or black with faint white tip, except for reddish- and yellowish-brown (similar to back) at base; undersurface similar to uppersurface. Skull long (35.9 mm), angular and broad (20.9 mm), with moderately long rostrum (15.6 mm) and anterior palatal foramina (4.3 mm). Upper tooththrow (5.3 mm) relatively long. Auditory bullae long (11.7 mm) and inflated (mastoid breadth 17.3 mm) relative to skull length (measurements listed are mean values from Libya [Kahmann & Thoms 1981]). Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Eliomys munbyanus. Smaller average head and body length (117 mm). Tail (108 mm), hindfeet (25 mm) and ears (24 mm) shorter. Dorsal pelage similar, postauricular patches usually more conspicuous. Tail not bushy; black with conspicuous white at tip. Ventral tail colour uniformly pale grey or brownish-white from base to tip in some populations. Skull slightly shorter (33.6 mm) with shorter rostrum (14.7 mm). Upper tooththrow shorter (4.7 mm), and auditory bullae shorter (10.2 mm) and less inflated (mastoid breadth 16.8 mm) both absolutely and relatively (measurements listed are mean values from Morocco [Kahmann & Thoms 1981]). Not sympatric, although both species occur in Libya.

Distribution Mediterranean Coastal BZ and northern margins of Sahara Arid BZ. Recorded from Libya, eastwards from Barqah (Cyrenaica) and Egypt including the Sinai Peninsula (Holden 2005). Extraliminally known from the Middle East, Iraq and southern Turkey.

Habitat Coastal dunes and adjacent inland plateaux, Mediterranean scrubland, escarpments, steppe-deserts, rocky areas, mountains, gardens and human dwellings (Flower 1932, Wassif & Hoogstraal 1953, Ranck 1968, Osborn & Helmy 1980, Harrison & Bates 1991). Other

habitat records include limestone cliffs in coastal desert (Osborn & Helmy 1980), on upper slopes of a wadi near coastal escarpment under a large evergreen bush (Setzer 1957), in a small mountainside garden at 1700 m, near a spring in a garden, and in a Bedouin tent (Wassif & Hoogstraal 1953). In eastern North Africa, captured at elevations from sea level to 1700 m (Harrison & Bates 1991).

Abundance Little information. Probably uncommon in eastern North Africa, based on the low numbers of specimens obtained at individual localities, as well as collectors' notes (Setzer 1957, Ranck 1968). In Israel, trap success during one night in spring (Mar–May) was 11.7%; in other seasons at the same localities the animals were uncommon (Haim & Rubal 1995).

Adaptations Arboreal and terrestrial; nocturnal (Haim & Rubal 1995, Qumsiyeh 1996). Resting metabolic rate is relatively low. Daily energy expenditure is conserved by entering torpor even when T_a is as high as 25 °C (Haim & Rubal 1995). In the Negev Highlands, T_a ranges from above 30 °C to below 0 °C during the winter; dormice trapped in winter at ambient temperatures close to 0 °C were found in traps in torpor with a T_b of 12 °C; torpor can last up to several days (Haim & Rubal 1995).

Foraging and Food Omnivorous, predominantly insectivorous and carnivorous. Stomach contents have included insects and other invertebrates, and occasionally small mammals and other small vertebrates (Atallah 1978, Nader *et al.* 1983, Qumsiyeh 1996). These dormice readily enter live-traps (Osborn & Helmy 1980).

Social and Reproductive Behaviour Little information. Osborn and Helmy (1980) characterized wild caught animals as extremely wild and aggressive.

Reproduction and Population Structure Apparently solitary. Mean litter-size in captivity: 2.8 (Kahmann & Thoms 1981, Kahmann 1987); no information for wild individuals. Gestation: ca. 22 days (in captivity; Kahmann & Thoms 1981). In Israel, a pregnant ♀ was captured in Apr, and a lactating ♀ was captured in May (Kahmann 1981). Sex ratio 40% ♂♂, 60% ♀♀ (Egypt; Osborn & Helmy 1980).

Predators, Parasites and Diseases Ectoparasites include the siphonapteran fleas *Myoxopsylla laverani*, *Nesophyllus henleyi* and *Xenopsylla ramesis* (Hoogstraal & Traub 1965b, Krasnov *et al.* 1999). Mites (not identified) were collected from some individuals collected in Saudi Arabia (Nader *et al.* 1983). In Israel, skeletal remains were found in pellets of Barn Owls *Tyto alba*; in Syria, skeletal elements were identified in pellets of Barn Owls and Long-eared Owls *Asio otus* (Obuch 2001).

Conservation IUCN Category: Least Concern.

Eliomys munbyanus MAGHREB GARDEN DORMOUSE

Fr. L  rot Nord-africain; Ger. Nordafrikanischer L  ffelbilch

Eliomys munbyanus (Pomel 1856). Comptes Rendus de l'Academie des Sciences, Paris 42: 653. Region d'Oran (Province of Oran), Algeria.

Taxonomy Originally described in genus *Myoxus*. *Eliomys munbyanus* has historically been considered a synonym of *E. quercinus* (Niethammer 1959, Kry  tufek & Kraft 1997), although Filippucci *et al.* (1988a, b), Filippucci & Kotsakis (1995) and Filippucci & Capanna (1996) considered *munbyanus* to be synonymous with the Middle Eastern *E. melanurus*, an arrangement tentatively followed by Holden (1993). A few authors have suggested recognizing certain North African populations as a separate species, utilizing the names *E. munbyanus* (Delibes *et al.* 1980) or *E. tunetae* (Tranier & Petter 1978). Holden (2005) argues that recent morphometric analyses (Kry  tufek & Kraft 1997), considered together with karyologic and allozymic analyses (Delibes *et al.* 1980, Filippucci *et al.* 1988a, b, Filippucci & Kotsakis 1995, Filippucci & Capanna 1996), support the recognition of *E. munbyanus* as a separate species that is probably closely related to *E. melanurus*. The assignment of synonyms and geographic distributions are based primarily on the results of Kry  tufek & Kraft's (1997) morphological study. Additional genetic and karyological sampling of *E. munbyanus* and North African *E. melanurus* populations is needed. Only the Moroccan population of *E. munbyanus* has been sampled for allozyme variation, and karyological data have only been reported from Moroccan and Tunisian populations. The hypothesized distribution of *E. munbyanus* is concordant with that of other mammalian endemics of the Maghreb (see Carleton & Van der Straeten 1997). Synonyms: *denticulatus*, *lerotina*, *occidentalis*, *tunetae*. Subspecies: none. Chromosome number: 2n = 46 (Tranier & Petter 1978, Delibes *et al.* 1980, Moreno & Delibes 1982, Filippucci *et al.* 1988a, Zima *et al.* 1995).

Description Medium-sized dormouse. Dorsal pelage reddish- or yellowish-brown suffused with grey. Pelage soft, sometimes woolly and moderately long (rump hairs 10–11 mm, guard hairs up to 16 mm). Ventral pelage white slightly suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage; paler towards muzzle. Eyes large; dark eye-mask conspicuous. Cheeks cream or white, forming part of a pale lateral stripe that extends from cheeks to shoulders. Ears moderately large, brown, oval-shaped. White or reddish postauricular patches usually present. Hindfeet white. Tail long (ca. 92% of HB), tail hairs shorter at base (3–4 mm) and longer at tip (up to 19 mm); dorsally black with white at tip, except for reddish- and yellowish-brown (similar to back) at base; ventrally either uniformly pale grey or brownish-white, or pale grey or brownish-white at base with a black middle section and white tip. Skull moderately long (33.6 mm), angular and broad (19.5 mm), with moderately short rostrum (14.7 mm) but comparatively long anterior palatal foramina (4.3 mm). Upper

toothrow (4.7 mm) relatively short. Auditory bullae moderately long (10.2 mm) and moderately inflated (mastoid breadth 16.8 mm) relative to skull length (measurements listed are mean values from Morocco [Kahmann & Thoms 1981]). Nipples: 1 + 1 + 2 = 8.

Geographic Variation Ventral tail colour and pattern varies geographically. In Western Sahara and SW Morocco, the ventral tail colour is white or grey proximally, changing to solid black in the middle section, with a conspicuous white tip. The black region of the tail is sometimes fringed in white. Specimens collected from other regions of Morocco and Algeria have a totally greyish-white or white ventral tail colour (similar to European *E. quercinus*). Individuals from Tunisia and W Libya exhibit the same pattern as those from Western Sahara and SW Morocco (Kahmann & Thoms 1981). Tail length and body size also appear to vary among some populations. Populations from N Morocco have a longer tail length (tail length exceeds that of head and body) than surrounding populations (Moreno & Delibes 1982). This population also exhibits smaller body size (reflected in shorter HB and GLS lengths), and less inflated auditory bullae compared with populations from southern Morocco and Algeria (Cabrera 1932, Saint-Girons & Petter 1965, Moreno & Delibes 1982, Aulagnier & Th  venot 1986).

Similar Species (size comparisons refer to mean values only)

Eliomys melanurus. Larger average head and body length (128.0 mm). Tail (122.0 mm), hindfeet (26.7 mm) and ears (27.0 mm) longer. Dorsal pelage similar, postauricular patches usually less conspicuous. Tail bushy; distal dorsal colour uniformly black, or black with faint white tip. Ventral tail colour not paler, and does not vary significantly geographically. Skull slightly longer (35.9 mm) and longer rostrum (15.6 mm). Upper tooththrow longer (5.3 mm) and auditory bullae longer (11.7 mm) and more inflated (mastoid breadth 17.3 mm), both absolutely and relatively (measurements listed are mean values from Libya – see Measurements). Not sympatric, although both species occur in Libya.

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded from Western Sahara, Morocco, Algeria, Tunisia and Libya (as far east as the Tar  bulus region of Tripolitania) (Holden 2005). One population in the Sahara Arid BZ in the Fezzan. Recorded from sea level up to 3800 m.

Habitat Captured in thick Mediterranean scrubland comprised of heath (*Arbutus*, *Calluna*, *Erica*), mock privet *Phillyrea*, pistachio

*Eliomys munbyanus*

Pistacia, myrtle *Myrtus*, Mediterranean fan palm *Chamaerops*; young cork oak *Quercus suber*; pine plantations (*Pinus halepensis*, *P. insignis*); mixed oak forests (*Quercus canariensis*, *Q. pyrenaica* and *Q. suber*); dry, overgrazed habitats with isolated *Acacia*, pistachio and Mediterranean fan palm (Saint-Girons & Petter 1965, Moreno & Delibes 1982); large oases and adjoining areas in or near date palms *Phoenix* and tamarisk *Tamarix* (Ranck 1968); potato fields (Khidas 1993); and occasionally in prickly pear cactus *Opuntia* (Kahmann & Thoms 1981). Other habitats include coastal dunes, montane cedar forests, montane boulder fields and cultivated areas (Ranck 1968, Kahmann & Thoms 1981, Moreno & Delibes 1982, Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991). In the Fezzan, captures were in or adjacent to oases.

Abundance Uncommon (Ranck 1968, Moreno & Delibes 1982, Aulagnier & Thévenot 1986, Khidas 1993).

Adaptations Predominantly arboreal, partly terrestrial; nocturnal (Kahmann & Thoms 1981, Aulagnier & Thévenot 1986). Often enter torpor in winter in response to prolonged cooler ambient temperatures (Kahmann & Thoms 1981). In Libya, individuals were infrequently captured during the winter months when ambient temperatures at night often dropped below -1°C ; Ranck (1968) suggested that the seemingly low abundance might be explained by inactivity of torpid individuals. In Morocco, one individual was caught during a night during which the ambient temperature dropped below 0°C (Moreno & Delibes 1982). Nests have been found in many situations: in holes in trees (including tamarisk, olive, willow, poplar and several species of palm), in shrubs (small palms, and rarely prickly pear cactus), in rock crevices, caves and at the bases of large rocks, and in thatched roofs, alcoves, attics and conduits of huts (Ranck 1968, Kahmann & Thoms 1981). Materials used to construct nests include grass, barley stems, palm fibre, goat hair, sheep and possibly dromedary wool, and even flower clusters of *Acacia* (Pomel

1856, Ranck 1968, Kahman & Thoms 1981). Kahmann & Thoms (1981) stated that the primary physical requirement of a nest is to provide all-round body contact.

Foraging and Food Probably omnivorous, consuming fruit, insects, seeds and sometimes eggs. In Tunisia, reported to be a pest in fruit plantations (favouring pomegranate) and in vegetable gardens (legumes, paprika, eggplant); may also eat chicken eggs (Kahmann & Thoms 1981). Kahmann & Thoms (1981) attempted stomach analyses of 11 individuals from Cap Bon, Tunisia, but were unsuccessful. Remains of insects and land snails were found near nest entrances in rocky fields, and individuals were observed capturing butterflies by springing into the air with both forelimbs stretched out in front (Kahmann & Thoms 1981). Bait made from bread dipped in cooking oil (Morocco; Moreno & Delibes 1982) and moistened oatmeal (Libya; Ranck 1968) attracted these dormice.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Solitary. Reproductively active in spring and, at lower altitudes, autumn (Kahmann & Thoms 1981, Moreno & Delibes 1982). Litter-size: probably 4–6, although one pregnant ♀ contained eight embryos (Kahmann & Thoms 1981, Moreno & Delibes 1982). Young stay in the nest for approximately seven weeks (Kahmann & Thoms 1981). In N Morocco, lactating ♀♀ were captured in Nov (Moreno & Delibes 1982). In Tunisia, two pregnant ♀♀ were collected in Mar, and one pregnant ♀ was captured in Apr (Kahmann & Thoms 1981). In Tunisia, sex ratio was found to be male-biased, but this may reflect a sampling artefact due to seasonal differences in activity between sexes (Kahmann & Thoms 1981).

Predators, Parasites and Diseases Principal host for the hoplopleurid louse *Schizophthirus pleurophaeus* (Durden & Musser 1994). In Algeria, skeletal remains were identified in owl pellets (Kowalski & Rzebik-Kowalska 1991) and in the scat of a jackal (Khidas 1986).

Conservation IUCN Category: Least Concern.

GENUS *Graphiurus*

African Dormice

Graphiurus Smuts, 1832. Enumer. Mamm. Capensium, pp. 32–33. Type species: *Sciurus ocularis* Smith, 1829.

Graphiurus murinus.

Figure 19. Skull and mandible of *Graphiurus nagtglasii* (RMCA RG 5556).

The 14 living species of the genus *Graphiurus* occur throughout sub-Saharan Africa in tropical lowland rainforest, montane evergreen and semi-deciduous forest, moist and arid savanna woodlands and grasslands, as well as the Nama- and succulent-Karoo biomes and fynbos in southern Africa. Treeless deserts, such as the Namib, are devoid of dormice, except near oases. Primary habitat requirements for African dormice are trees, woody vines, bushes and weathering granitic outcrops (kopjes) that provide shelter and nesting sites.

The genus is characterized externally by a generally plain-coloured face without obvious markings in most species (except *G. ocularis*), and the colour of the tail and tail tip. The skull is distinguished by a short, often broad rostrum, very narrow zygomatic plate that is situated entirely beneath the infraorbital foramen, modified hystricomorphous zygomatic muscle arrangement, differences in position of certain cranial foramina, V-shaped cutting edges of incisor tips (forming a V-shaped notch from anterior view) in most species, and indistinct, usually incomplete lophs or ridges on cheekteeth (Ellerman 1940, Wahlert *et al.* 1993, Nowak 1999) (Figure 19). Many closely related species of *Graphiurus* are difficult to distinguish, although a few species are easy to identify because of their unique prominent characters: *G. crassicaudatus* has a broad interorbital constriction and pronounced supraorbital ridging, and *G. nagtglasii* is the largest species and has a distichous tail. Species that typically dwell in rock crevices, such as *G. platyops* and *G. ocularis*, have a flattened cranium that is easily distinguished from the vaulted cranium found in all other species. *Graphiurus ocularis* is also easily identified by its striking facial colour pattern and its reduced, circular premolar.

In their morphology and habits, all sub-Saharan African dormice resemble small-bodied arboreal squirrels, and like these animals all species of *Graphiurus* are arboreal; even those using crevices in rocky habitats, such as kopjes, for nesting sites are excellent climbers. All species are nocturnal, although at least one species (*G. platyops*) has also been documented to be active at dawn (Wilson 1975), and another species (*G. angolensis*) was reportedly active during the day (field notes; specimen labels). Most species are omnivorous, and consume fruits, insects, seeds and nuts; *G. ocularis* is predominantly insectivorous (Channing 1984). Some species, such as *G. lorrainus* and *G. murinus*, enter torpor during periods of low ambient temperature and inadequate food supply (Lachiver & Petter 1969, Webb & Skinner 1996b).

Hartenberger (1994) considered many aspects of graphiurine morphology to be primitive, and speculated that the group has been in Africa since the Miocene; late Miocene graphiurines are recorded from Namibia (Mein *et al.* 2000b) and South Africa (Denys 1990b). Mein *et al.* (2000b) described the late Miocene *Otaviglis* from Namibia as the oldest known graphiurine (10–11 mya), possibly derived from the middle Miocene *Microdryomys* found in North Africa, and suggested it could be ancestral to *Graphiurus*. Molecular-clock calibrations derived from phylogenetic analyses of nuclear and mitochondrial gene sequences indicate that the adaptive radiation within *Graphiurus* occurred 8–10 mya, which pre-dates the oldest

fossil representative of the genus (early Pliocene, ca. 5 mya), but is consistent with the late Miocene graphiurine records (Montgelard *et al.* 2003). The time frame also brackets a period of low sea levels and extensive interchange of faunas between Europe and Africa. Following the colonization of Africa by a late Miocene ancestor, graphiurines underwent an adaptive radiation resulting in a modern fauna that is richer in species than those in all the other genera of dormice combined (Montgelard *et al.* 2003).

The taxonomic revision of extant *Graphiurus* by Genest-Villard (1978a) was based mostly on size grades and underestimated species diversity, particularly in *G. murinus* and closely related species. Subsequently, certain species were defined in reports covering different geographical regions (e.g. Robbins & Schlitter 1981, Ansell & Dowsett 1988, Holden 1996). Profiles of the 14 species in this volume are based on literature sources, examination of museum specimens and preliminary multivariate analyses of cranial and dental measurements (M. E. Holden unpubl.). It is likely that future studies that incorporate molecular data will show that some species recognized here actually contain two or more separate species.

Graphiurus has been divided into as many as four separate genera (e.g. Allen 1939, Holden 1996, Pavlinov & Potapova 2003): *Aethoglis*, containing the largest African dormouse *G. nagtglasii* (sometimes erroneously including *G. monardi*); *Graphiurus* comprising *G. ocellaris*, with its reduced, simple upper premolar; *Gliriscus* consisting of the rupicolous *G. platyops* and *G. rupicola*; and *Claviglis* the so-called

‘tree dormice’, to which the remaining species of *Graphiurus* were assigned. Two of these, *Graphiurus* and *Claviglis*, have often been retained as subgenera (e.g. Ellerman *et al.* 1953, Rosevear 1969). No published studies based upon a broad sample of species have addressed the validity of these subgeneric boundaries as used by past authorities, nor have they presented hypotheses of relationships among species. However, phylogenetic analyses of cranial and middle ear morphology by Pavlinov & Potapova (2003) identified three monophyletic groups (subgenera) within *Graphiurus*: *Aethoglis* (containing *G. nagtglasii*), *Claviglis* (containing *G. crassicaudatus*) and *Graphiurus* (containing all other *Graphiurus* species). Their study suggested that first *G. nagtglasii*, then *G. crassicaudatus*, diverged early in the evolution of African Dormice, and that the remaining taxa that they sampled (*angolensis*, *christyi*, *kelleni*, *lorraineus*, *murinus*, *ocellaris*, *parvus* and *surdus*) form a separate monophyletic group. Pavlinov & Potapova’s (2003) subgeneric arrangement is followed by Holden (2005). Here, the species are listed alphabetically.

The 14 species are distinguished externally by body size, length of tail, ear and hindfoot, degree of conspicuousness of eye-mask, and colour of the tail tip. The skulls are differentiated by the overall shape of the skull, the shape of the zygomatic arch, presence/absence of supraorbital ridges, length and relative inflation of auditory bullae, differences in toothrow measurements and relative size of the upper premolar, and several skull dimensions.

Mary Ellen Holden

Graphiurus angolensis ANGOLAN AFRICAN DORMOUSE

Fr. Graphiure d’Angola; Ger. Angolischer Bilch

Graphiurus angolensis de Winton, 1897). Ann. Mag. Nat. Hist., ser. 6, 20: 320. Caconda, Angola.

Taxonomy Originally described in the genus *Gliriscus*. Allen (1939) recognized *G. angolensis* as a species distinct from *G. platyops*, *G. rupicola* and *parvulus*. Ellerman *et al.* (1953) included *G. angolensis*, *G. rupicola* and *parvulus* as subspecies of *G. platyops*. Genest-Villard (1978a) placed *G. rupicola* as a subspecies of *G. platyops*, but synonymized *G. angolensis* and *parvulus* under *G. murinus*. Ansell (1974, 1978) recognized that the north-western Zambian population (identified by him as *G. platyops parvulus*) is morphologically and ecologically different from *G. platyops*. Holden (1993) provisionally listed populations from Angola, S DR Congo and NW Zambia under *G. platyops*. Populations in Angola and NW Zambia exhibit a distinctive skull morphology that is consistently separable from that of *G. platyops* and *G. rupicola* (M. E. Holden unpubl.). Ansell (1974, 1978) had correctly surmised that these populations are probably aligned with *G. microtis*. Here, following Allen (1939), *G. angolensis* is considered as a valid species and distinct from *G. platyops* and *G. rupicola*. The form *parvulus* (as described by Monard 1933) is probably a junior synonym of *G. angolensis* (Holden 2005). Synonyms: *dasilvai*, *parvulus*. Subspecies: none. Chromosome number: not known.

Description Small dormouse. Dorsal pelage dark brown, rufous, golden, or drab brown, with darkening of pelage towards the mid-line of head and back in some individuals. Dorsal pelage soft, sleek, thick and moderately long (rump hairs 8 mm, guard hairs up to 12 mm).

Ventral pelage white or cream slightly suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage, slightly paler towards muzzle. Eyes large; eye-mask conspicuous. Ears brown, large, rounded. Cheeks cream or white, forming part of a pale lateral stripe that extends from cheeks to shoulders. Cream postauricular patches usually present. Hindfeet white, or white with dark metatarsal streak. Tail moderately long (ca. 80% of HB), tail hairs shorter at base (5–10 mm) and longer at tip (up to 33 mm). Tail colour generally matches dorsal pelage. White hairs are mixed throughout tail; tip white. Skull long, robust and moderately broad (15.5 mm), with a relatively vaulted braincase (height of braincase 7.7 mm). The appearance of a vaulted braincase is augmented by the concave curvature of the braincase (lateral view) and large auditory bullae. Interorbital constriction moderately narrow (4.2 mm), anterior palatal foramina comparatively long (3.4 mm) and wide (2.1 mm), and auditory bullae long (9.0 mm) and inflated relative to skull length (mean values from Kabompo and Zambezi [formerly Balovale], Zambia; M. E. Holden unpubl.). Nipples: 1 + 1 + 2 = 8.

Geographic Variation Individuals from C Angola are notably darker and usually exhibit a dark metatarsal streak on the hindfeet, whereas individuals from S and C Angola (type locality of *parvulus*) and Zambia are drab or golden brown, usually with white hindfeet.

Ear pinnae shorter (on average) in Angolan specimens (13.5 mm) than in Zambian specimens (15.9 mm) (mean values from Ondjiva and Caconda, Angola, and from Kabompo and Zambezi [formerly Balovale], Zambia; M. E. Holden unpubl.).

Similar Species (size comparisons refer to mean values only)

Graphiurus microtis. Similar mean head and body length (98.8 mm).

Tail (mean 75.2 mm) and hindfeet (mean 16.9 mm) absolutely and relatively shorter. Dorsal pelage often similar in colour, but grey in some populations. Skull similar in length (27.4 mm), but slightly narrower (15.0 mm). Interorbital constriction (3.9 mm) slightly narrower. Anterior palatal foramina 3.4 mm long, 2.1 mm wide. Mean upper tooththrow length (3.0 mm) shorter, and mean upper premolar breadth (0.8 mm) narrower. Auditory bullae (8.1 mm) absolutely and relatively shorter and less inflated (measurements listed are mean values from Zimbabwe; M. E. Holden unpubl.). Parapatric in NW Zambia (Ansell 1978). *Graphiurus microtis* occurs in savannas throughout most of sub-Saharan Africa.

Graphiurus rupicola. Slightly larger head and body length (mean 110 mm). Tail (mean 104.2 mm) and hindfeet (mean 21.5 mm) absolutely and relatively longer. Dorsal pelage grey. Mean skull length slightly longer (31.3 mm). Interorbital constriction broader (5.0 mm) and palate longer (10.4 mm) both absolutely and relatively. Braincase absolutely more vaulted (8.0 mm), but flatter relative to skull length. Anterior palatal foramina 3.4 mm long, 2.3 mm wide. Upper tooththrow (3.4 mm) similar in absolute length, but shorter relative to skull length (measurements listed are mean values from Erongo, Karibib and Mt Brukkaros, Namibia; M. E. Holden unpubl.). Parapatric in Angolan highlands; also occurs in Namibia and NW South Africa.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded only from C and S Angola and NW Zambia (Holden 2005).

Graphiurus angolensis

Habitat Little information. Woodland savanna. Most collecting localities in Angola are in or near wetter miombo woodland, and in wetter miombo woodland and Zambezian dry evergreen forest in Zambia. Individuals have also been captured in human dwellings.

Abundance Common in the Kabompo and Zambezi districts of Zambia (Ansell 1978). The species is probably common in the interior plateaux region of Angola (Bocage 1890, Hill & Carter 1941).

Adaptations Arboreal, probably nocturnal. (Most species of African Dormice are nocturnal.) Some individuals of this species were noted to be active during the day in C Angola (field notes; specimen labels). These dormice have most often been caught in trees; in Angola, they were also found in abandoned beehives (field notes; specimen labels). In Zambia, they have sometimes been captured in buildings; one ♀ with young was caught in the roof of an African hut, another solitary ♀ was caught among some planks in a carpenter's shop, and one ♂ was obtained in a store (Ansell 1978; specimen labels).

Foraging and Food Probably omnivorous. Little is known regarding the diet. An individual captured in Angola was recorded to have eaten tree grubs and the fruit of a 'parasitic growth on trees' (field note, Phipps-Bradley Angola Expedition). One individual was caught in a trap baited with meat (Chubb 1909).

Social and Reproductive Behaviour Little information. Lactating ♀♀ are often caught with young. One ♀ was recorded as being caught 'with four half-grown young, but apparently no longer lactating' (specimen label). Monard (1935) states that Angolan Dormice are aggressive.

Reproduction and Population Structure Litter-size: probably 3–5 (Ansell 1963; specimen labels). In Zambia, a ♀ captured in late Oct gave birth the following day to three young (Ansell 1963).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Data Deficient.

Graphiurus christyi CHRISTY'S AFRICAN DORMOUSE

Fr. Graphiure de Christy; Ger. Christys Bilch

Graphiurus christyi Dollman, 1914. Revue Zoologique Africaine 4 (1): 80. Mambaka, DR Congo.

Taxonomy Morphologically similar to some named forms currently synonymized under *G. murinus*, some of which occur in areas adjacent to this species, e.g. *vulcanicus* from the Virunga Mts. Other named forms synonymized under *G. murinus* that occur in adjacent areas are morphologically distinct, e.g. *soleatus*, from the Rwenzori Mts. Synonyms: none. Chromosome number: not known.

Description Small dormouse. Dorsal pelage medium brown, rufous-brown or rufous golden-brown. Dorsal pelage soft, silky and moderately thick (rump hairs 6–8 mm, guard hairs up to 11 mm). Ventral pelage grey washed with white. Dorsal and ventral pelage colours not clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask usually conspicuous. Ears brown, large, rounded. Cheeks usually white. Postauricular patches not present. Hindfeet white with dark metatarsal streak. Tail moderately long (ca. 82% of HB), hairs shorter at base (3–5 mm) and longer at tip (up to 21 mm). Tail colour generally matches that of dorsal pelage and does not exhibit white tip. Skull medium length (28.0 mm), moderately narrow (15.1 mm) and moderately vaulted (height of braincase 8.1 mm). Interorbital constriction (4.7 mm) narrow. Supraorbital ridges present. Premaxilla and nasal bones often extend farther beyond the anterior face of the incisors than in similar species. Anterior palatal foramina moderately long (mean 3.0 mm) and wide (mean 2.2 mm), palate moderately long (8.5 mm), auditory bullae short (7.4 mm) and not inflated relative to skull length. Anterior chamber of auditory bullae markedly less inflated than posterior chambers in some individuals (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus lorraineus. Smaller head and body length (mean 83 mm), ears shorter (mean 12.1 mm). Dorsal pelage usually more rufous. Skull (24.5 mm) shorter and anterior palatal foramina narrower (1.7 mm) relative to skull length. Nasals and premaxilla usually do not extend as far beyond incisors. Palate absolutely shorter (7.8 mm) but relatively similar. Anterior palatal foramina 2.7 mm long, 1.7 mm wide. Auditory bullae similar in length (7.2 mm), but longer relative to skull length (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). Sympatric in SW Cameroon and NE DR Congo. Occurs in West and central Africa.

Graphiurus surdus. Similar mean head and body length (99.0 mm), ears shorter (mean 12.3 mm). Dorsal pelage usually greyish-brown, not rufous. Tail (mean 72 mm) absolutely and relatively shorter (ca. 73% of HB). Zygoma robust, and the anterior, superior margins are relatively straight when viewed from side (see Holden 1996). Palate longer (9.3 mm); anterior palatine foramina absolutely and relatively shorter (2.8 mm) and narrower (1.8 mm) (measurements listed are mean values from Cameroon, Equatorial Guinea and Gabon; Holden 1996). Not sympatric,

*Graphiurus christyi*

although both species have been collected in SW Cameroon and N DR Congo.

Graphiurus crassicaudatus. Smaller head and body length (mean 92.6 mm). Dorsal pelage rufous-brown, similar to some individuals of *G. christyi*. Skull shorter (26.6 mm). Breadth of skull (16.1 mm) and interorbital constriction (4.9 mm) markedly broader relative to skull length. Supraorbital ridges present. Anterior palatal foramina absolutely and relatively shorter (2.5 mm) and narrower (1.6 mm). Palate (9.4 mm) and upper toothrow (3.8 mm) absolutely and relatively longer (measurements listed are mean values from S Cameroon; M. E. Holden unpubl.). Not sympatric, though their distributions overlap in SW Cameroon; occurs in West and west-central Africa.

Distribution Endemic to Africa. Recorded from Rainforest BZ (mainly East Central Region) with one outlier in West Central Region. Recorded from NE DR Congo (many localities, all north of the Congo and Lualaba rivers) and SW Cameroon (one locality). A specimen from Inkongo, C DR Congo, identified as this species (Hatt 1940a) is, in fact, a specimen of *G. surdus* (Holden 1996).

Habitat Rainforest. According to Hatt (1940a), these dormice occur in high forest.

Abundance Little information and rarely encountered. The Lang–Chapin Congo Expedition collected 29 specimens at Medje, DR Congo, but caught only one specimen at each of the three other localities where they encountered this species. Robbins & Schlitter

(1981) obtained four individuals from Lolodorf, SW Cameroon, and Schlitter *et al.* (1985) collected eight individuals from Yalosemba, DR Congo.

Adaptations Arboreal and probably nocturnal. Nests in hollow trees (Hatt 1940a).

Foraging and Food Probably omnivorous, eating fruit, insects, seeds and nuts. Notes taken by the Lang–Chapin Congo Expedition indicated that the stomachs of four individuals contained ‘a whitish or somewhat greenish paste-like vegetable matter’ (Hatt 1940a).

Social and Reproductive Behaviour In DR Congo, five individuals were collected from a hollow tree that contained no nest: two ♂♂, two ♀♀ and one escaped (Hatt 1940a).

Reproduction and Population Structure Litter-size: probably 2–3 (Hatt 1940a). In DR Congo, a ♀ was found in Jan with two young (eyes closed); two additional young (eyes closed) were collected from a separate nest; and one pregnant ♀ contained three embryos (Hatt 1940a).

Predators, Parasites and Diseases Little information. Some specimens in museum collections have several louse exoskeletons attached to pelage and tail hairs

Conservation IUCN Category: Least Concern.

Graphiurus crassicaudatus THICK-TAILED AFRICAN DORMOUSE

Fr. Graphiure à grosse queue; Ger. Dickschwanz-Bilch

Graphiurus crassicaudatus (Jentink, 1888). Notes from the Leyden Museum 10: 41–42. Hill Town, Du Queah River, Liberia.

Taxonomy Originally described in the genus *Claviglis*. Rosevear (1969) and Holden (1996) hypothesized that the morphological similarity between *G. crassicaudatus* and *G. nagtglasii* (formerly *G. hueti*) indicated a close phylogenetic relationship between the two species. In contrast, recent cladistic analysis of African dormice based on cranial and middle ear characters does not support this conclusion (Pavlinov & Potapova 1993, see also Holden 2005). Synonyms: *dorotheae* (see Allen 1939, Rosevear 1969). Subspecies: none. Chromosome number: not known.

Description Small dormouse. Dorsal pelage usually rufous-brown. Pelage soft and short (rump hairs 4–5 mm, guard hairs up to 10 mm). Ventral pelage grey washed with ochre, cream or white. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage; muzzle short. Eyes large; eye-mask conspicuous in some individuals. Ears brown, short and rounded. Postauricular patches usually not present. Hindfeet white, or white with a dark metatarsal streak. Tail short (ca. 65% of HB), hairs shorter at base (3–4 mm) and longer at tip (up to 27 mm). Tail colour generally matches that of dorsal pelage. A few white hairs are mixed throughout the tail, but tip is not white. Skull broad (16.1 mm), with vaulted braincase (height of braincase 7.9 mm) and conspicuously wide interorbital constriction (4.9 mm) with supraorbital ridges. Anterior chamber of auditory bullae usually markedly less inflated than posterior chambers. Zygomatic arches flare out at a 90 degree angle from the rostrum. Rostrum short and narrow, with short nasal bones (8.9 mm). Anterior palatal foramina comparatively short (mean 2.5 mm) and very narrow (mean 1.6 mm) relative to skull

length. Palate (9.4 mm) and upper toothrow (3.8 mm) relatively long (measurements listed are mean values from southern Cameroon; M. E. Holden unpubl.). Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus lorraineus. Smaller head and body length (mean 83.0 mm). Dorsal pelage similar in colour. Skull shorter (24.5 mm) and narrower (13.8 mm), with much narrower interorbital constriction (4.3 mm) and without supraorbital ridges. Anterior palatal foramina 2.6 mm long, 1.7 mm wide. Palate (7.8 mm) and upper toothrow (3.1 mm) absolutely and relatively shorter, auditory bullae similar in length (7.2 mm), but relatively longer (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). Sympatric at several localities in Liberia, Côte d’Ivoire and S Cameroon; occurs in West and central Africa.

Graphiurus surdus. Larger head and body length (mean 99.0 mm), with longer hindfeet (mean 20.8 mm). Dorsal pelage greyish-brown, with no rufous hue. Skull narrower (14.6 mm), with narrower interorbital constriction (4.5 mm) and without supraorbital ridges. Anterior palatal foramina 2.8 mm long, 1.8 mm wide. Upper toothrow (3.2 mm) absolutely and relatively shorter (measurements listed are mean values from Cameroon, Equatorial Guinea and Gabon; Holden 1996). Sympatric in SW Cameroon, also occurs in DR Congo.

Graphiurus christyi. Larger head and body length (mean 97.6 mm). Dorsal pelage sometimes similar in colour. Skull slightly longer

(28.0 mm). Breadth of skull (15.1 mm) and interorbital constriction (4.7 mm) narrower relative to skull length, and without supraorbital ridges. Anterior palatal foramina absolutely and relatively longer (3.0 mm) and wider (2.2 mm). Palate (8.5 mm) and upper toothrow (3.2 mm) absolutely and relatively shorter (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). No records of sympatry, though geographic range overlaps in SW Cameroon; also occurs in DR Congo.

Distribution Endemic to Africa. Rainforest BZ (Western and West Central Regions) and Northern Rainforest–Savanna Mosaic. Recorded from Liberia and Guinea east to SW Cameroon (excluding Benin) and Bioko I. (see Rosevear 1969, Eisentraut 1973).

Habitat In or near primary and secondary rainforest.

Abundance Uncommon. The species is represented by a total of approximately 50 museum specimens, and it is considered rare or at least difficult to trap (Heim de Balsac 1967a, Robbins & Schlitter 1981, Happold 1987, Grubb *et al.* 1998).

Adaptations Arboreal. Individuals have been collected from hollow trees, on horizontal branches and vines, among bushes, among rocks

and in grass near houses (Sanderson 1940, Rosevear 1969, Robbins & Schlitter 1981; specimen labels), and even in a hole in a concrete culvert under railway tracks (Schlitter *et al.* 1985). In Nigeria, Sanderson (1940) found large, spherical nests a few feet above the ground in dense vegetation and, in Cameroon, he found five individuals living in a nest in a hollow tree. This nest was made of dead leaves, and lined with fibre from a species of nut that lay in large quantities on the surrounding ground. (Rosevear 1969 correctly noted that the specimens Sanderson (1940) identified as *Claviglis spurrelli* and *Claviglis haedulus* actually represent *G. crassicaudatus*.) Captive animals adapted the nests of weaver-birds for their use (Rosevear 1969).

Foraging and Food Probably omnivorous, consuming nuts (Rosevear 1969, Robbins & Schlitter 1981), insects (Rosevear 1969) and probably fruit.

Social and Reproductive Behaviour In Cameroon, Sanderson (1940) reported five adults in the same nest in a hollow tree. Two ♀♀ were caught, the other three escaped. This species bred readily in captivity (Rosevear 1969).

Reproduction and Population Structure No information.

Predators, Parasites and Diseases An ectoparasitic hoplopleurid louse, *Schizophthiris* sp., has been recorded on this species in Liberia (Kuhn & Ludwig 1965).

Conservation IUCN Category: Data Deficient.

Graphiurus johnstoni JOHNSTON'S AFRICAN DORMOUSE

Fr. Graphiure de Johnston; Ger. Johnstons Bilch

Graphiurus johnstoni Thomas, 1898. Proc. Zool. Soc. Lond. 1897: 934. Zomba, Malawi.

Taxonomy Ansell & Dowsett (1988), Ansell (1989b), Happold & Happold (1989a) and Holden (1993) synonymized *johnstoni* under *G. kelleni*. Recent re-examination and comparisons of museum specimens (including all holotypes), and preliminary multivariate

analyses, indicate that *G. johnstoni* is a separate valid species (M. E. Holden unpubl.). Morphologically, it is closely related to *G. lorrainae* and distinct from *G. kelleni*. Here, *G. johnstoni* is retained as a valid species, pending further revision of the genus (see also Holden

2005). Few specimens exist that can be attributed to *G. johnstoni* with certainty. If future research indicates that *G. johnstoni* and *G. lorrainaeus* are conspecific, the latter would be a junior synonym of *G. johnstoni*; this would substantially modify and enlarge the geographic range of what is now considered *G. johnstoni*. Synonyms: none. Chromosome number: not known.

Description Small dormouse. Dorsal pelage reddish-brown. Dorsal pelage soft and short (rump hairs 5–6 mm, guard hairs up to 8–9 mm). Ventral pelage grey, moderately suffused with buff or cream. Dorsal and ventral pelage colours not clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask inconspicuous. Ears brown, short and rounded. Cheeks cream or grey suffused with cream. Postauricular patches not present or inconspicuous. Hindfeet cream with dark metatarsal streak. Tail long (ca. 92% of HB), hairs shorter at base (2–3 mm) and longer at tip (up to 19 mm). Tail appears splayed because the hairs project laterally. Tail colour generally matches that of dorsal pelage and is uniform in colour, with sparse or no white hairs, and without white at tip. Skull short (23.6 mm), moderately vaulted (height of braincase 7.3 mm) and broad (13.9 mm) with relatively short rostrum (length of nasal bones 8.4 mm). Interorbital constriction broad (4.0 mm), tooththrow long (3.4 mm) and upper premolar wide (1.0 mm) relative to skull length. Anterior palatal foramina moderately long (2.7 mm) and moderately narrow (mean 1.7 mm) relative to skull length. Auditory bullae relatively short (6.8 mm) and moderately inflated. Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus lorrainaeus. Larger head and body length (mean 83.0 mm). Ear (12.6 mm) slightly larger. Tail relatively shorter (65.7 mm) with similar colouration. Dorsal pelage colour similar. Skull slightly longer (24.5 mm). Rostrum relatively short as in *G. johnstoni*, but length of nasal bones absolutely longer (9.1 mm). Anterior palatal foramina 2.6 mm long, 1.7 mm wide. Upper tooththrow slightly shorter (3.1 mm) and upper premolar narrower (0.8 mm). Not sympatric; *G. lorrainaeus* occurs in West and central Africa.

Graphiurus microtis. Larger head and body length (98.8 mm). Tail relatively shorter (75.2 mm), usually with white hairs mixed throughout, and with conspicuous white tip. Dorsal pelage colour sometimes similar, but beige or grey in some populations. Skull longer (27.4 mm) and wider (15.0 mm), auditory bullae longer (8.1 mm) and more inflated. Interorbital constriction (3.9 mm) similar in breadth, but relatively narrower. Anterior palatal foramina absolutely and relatively longer (3.4 mm) and wider (2.1 mm). Tooth row shorter (3.0 mm) both absolutely and relative to skull length. Sympatric in Thyolo, Malawi, but probably not syntopic; widespread in savannas of eastern and central Africa.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded only from S Malawi; limits of geographic range unknown.

Graphiurus johnstoni

Habitat Little information. Habitats on the Shire Highlands (ca. 900–1500 m) include sub-montane forests, miombo woodlands, farmlands, tobacco fields and secondary growth (Happold & Happold 1989a, b, 1997, 1998). Several specimens have been found in houses surrounded by ornamental gardens. Mean annual rainfall is ca. 1300 mm, with considerable annual variation.

Abundance No information. Rarely encountered.

Remarks Little information. Probably arboreal and nocturnal. Happold & Happold (1997) captured an individual in a farmhouse, indicating that this species may nest in human dwellings.

Conservation IUCN Category: Data Deficient.

Mary Ellen Holden

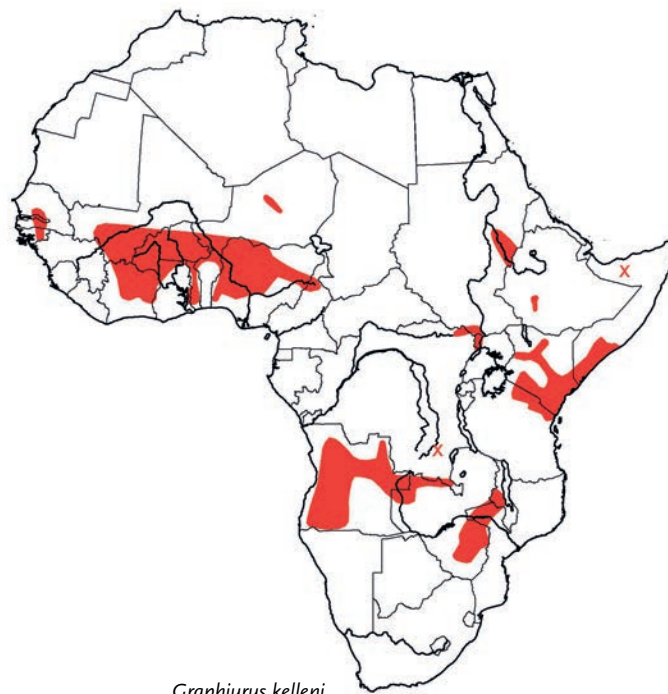

Graphiurus kelleni KELLEN'S AFRICAN DORMOUSE

Fr. Graphiure nain (Graphiure de Kellen); Ger. Kellens Bilch

Graphiurus kelleni (Reuvens, 1890). Notes from the Leyden Museum 13: 74. Reuvens originally listed Damaraland, Namibia, as the type locality; this was later emended to 'Damara-land', Mossamedes district, Angola (Hill and Carter 1941).

Taxonomy Originally described in genus *Eliomys*. Comparisons of museum specimens (including holotypes) and multivariate analyses of cranial morphology of *G. kelleni*, *G. parvus* and *G. olga* (M. E. Holden unpubl.) support the recognition of only one species (*G. kelleni*), and hence *olga* and *parvus*, previously considered as separate species (Holden 1993), are now placed as synonyms. These and other synonyms listed below have either been treated as separate species or included in species other than *G. kelleni* (see summary in Holden 1996, 2005). Ansell (1978) listed the species as *G. johnstoni* (recognized here as a separate valid species), but later (Ansell & Dowsett 1988, Ansell 1989b) referred to it as *G. kelleni*. The species requires taxonomic revision. Future studies will need to include larger samples, specimens from poorly collected localities and genetic data; such studies may well show that two or more separate species are contained within *G. kelleni*. No specimens of *G. kelleni* have been identified from South Africa (M. E. Holden unpubl.); however, some South African populations that are now placed in *G. murinus* are small in size. Future study and comparison of those populations may show that they are *G. kelleni* or an as yet undescribed species. Schlitter *et al.* (1985) discussed taxonomic problems and historical treatment of this species, and pointed out that *G. kelleni* is the oldest available scientific name. Synonyms: *ansorgei*, *brockmani*, *cuanzensis*, *dollmani*, *foxi*, *internus*, *nanus*, *olga*, *parvus*, *personatus*, *tasmani*. Subspecies: none. Chromosome number: $2n = 70$ (Dobigny *et al.* 2002b).

Description Small dormouse. Dorsal pelage various shades of brown, beige or grey, sometimes with golden or reddish hue, with darkening of pelage towards the mid-line of the head and back in some individuals. Dorsal pelage silky, sleek in some populations, thick in others (rump hairs 6–7 mm, guard hairs up to 11 mm). Ventral pelage usually white or cream, lightly or moderately suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour usually matches that of dorsal pelage, sometimes paler towards muzzle. Eyes large; eye-mask conspicuous. Ears brown, medium or large, rounded. Cheeks cream or white, forming part of a pale lateral stripe that extends from cheeks to shoulders. Cream or white postauricular patches usually present. Hindfeet white, or white with dark metatarsal streak. Tail moderately long (ca. 82% of HB), tail hairs shorter at base (2–3 mm) and longer at tip (up to 20 mm). Tail appears splayed in some populations (particularly in Angola, Zimbabwe and Zambia) because hairs project laterally. Dorsal tail colour matches that of dorsal pelage, often laterally fringed with white hairs and with faint or conspicuous white at tip. Ventral tail colour usually paler than dorsal tail colour. Skull short (24.0 mm), moderately vaulted (height of braincase 7.0 mm) and moderately broad (13.5 mm), sometimes gracile. Interorbital constriction moderately narrow (4.0 mm), anterior palatal foramina relatively long (2.9 mm) and auditory bullae long (7.8 mm) and inflated relative to skull length (measurements listed are mean values from Zambezi [formerly Balovale], Zambia; M. E. Holden unpubl.). Nipples: $1 + 1 + 2 = 8$.

*Graphiurus kelleni*

Geographic Variation Certain populations of *G. kelleni* exhibit variations in the colour and texture of dorsal pelage and in skull morphology that are consistent within these populations; e.g. in Somalia, dorsal pelage is sleek and pale reddish-tan; in montane populations in Kenya, dorsal pelage is thick and medium golden-brown. Some skulls in certain populations are very delicately built, others are robust; some are comparatively flat, others moderately vaulted; some have long and inflated auditory bullae, others exhibit short and only moderately inflated auditory bullae relative to skull length. On the basis of predominantly small sample sizes, and inadequate sampling over the vast geographic range of this species, preliminary morphometric analyses support the recognition of just a single species without subspecies.

Similar Species (size comparisons refer to mean values only)

G. microtis. Larger head and body length (mean 98.8 mm); ears longer (mean 15.5 mm). Dorsal pelage colour sometimes similar. Tail usually has white hairs mixed throughout, and conspicuous white tip. Skull longer (27.4 mm) and broader (15.0 mm). Anterior palatal foramina 3.4 mm long, 2.1 mm wide. Breadth of interorbital constriction (3.9 mm) and length of upper toothrow (3.0 mm) absolutely similar so relatively smaller in *G. microtis*. Auditory bullae absolutely slightly longer (8.1 mm), or of similar length in some populations, but relatively shorter. Sympatric in savannas throughout much of sub-Saharan Africa.

G. murinus. Larger head and body length (mean 91.5 mm). Hindfeet (18.5 mm) longer, ears (13.3 mm) absolutely and relatively

shorter. Dorsal pelage colour sometimes similar. Skull longer (26.4 mm), more vaulted (height of braincase 8.1 mm) and broader (14.2 mm). Interorbital constriction slightly broader (4.5 mm) and upper toothrow slightly longer (3.1 mm). Anterior palatal foramina 3.1 mm long, 1.9 mm wide. Auditory bullae shorter (7.1 mm) and less inflated relative to skull length (measurements listed are mean values from Mt Kenya; M. E. Holden unpubl.). Generally not sympatric, although they have been captured in close proximity at several Kenyan localities. Occurs in forests throughout much of sub-Saharan Africa.

Distribution Endemic to Africa. Recorded from parts of Sahel Savanna, Sudan Savanna, Guinea Savanna and Somalia–Masai Bushland BZs; also Zambezian Woodland BZ as far south as Angola, Malawi, Zimbabwe and Mozambique at altitudes up to 1524 m (Holden, 2005). Not recorded from Namibia, Botswana and South Africa.

Habitat Woodland savanna, riverine woodland, rocky areas including caves, disturbed areas and human dwellings. Specimens have been captured in or near dom palms (*Hyphaene thebaica*), thorn trees (*Acacia* spp.) and in miombo (*Brachystegia*) trees. Also occurs on mountains in East Africa (up to at least 1524 m), in rocky areas, and in caves (Osgood 1910, Dollman 1912, Hollister 1919; specimen labels). Less commonly found in disturbed areas, such as woodpiles, corn fields and in human dwellings (de Winton 1896, Stanley *et al.* 2002; specimen labels).

Abundance Little information. Comprised 1.7% of muroid and glirid rodents captured in savanna at Foro, Côte d'Ivoire, and 3.5% of muroid and glirid rodents captured in Guinea savanna in C Côte d'Ivoire (Gautun *et al.* 1991). Specimen labels from most localities indicate that the species is uncommon, but very large series from certain localities (e.g. C Angola, NE Zambia) indicate that it is common in at least certain parts of its range. No estimates of population density.

Adaptations Arboreal and nocturnal. These dormice frequently nest in crevices under bark, or in holes in savanna trees. Two nest holes were 0.5 m and 1 m above ground (specimen labels), and one nest was made of leaves and grass (Hill 1941). Several individuals were caught in nests of weaver-birds on *Acacia* trees and in the mud nests of swallows under roofs of caves or on undersides of rocks (Hollister 1919; specimen labels). Reported to utilize abandoned spider (*Stegodyphs* sp.) nests (Roberts 1951; specimen label) and abandoned beehives (Hill 1941). A few individuals have been caught in wood piles, in roofs of African huts and in pantries (Lawrence & Loveridge 1953; specimen labels).

Foraging and Food Probably omnivorous. In Somalia, one individual was caught in a trap baited with fresh meat (specimen label).

Social and Reproductive Behaviour Little information. Males are apparently solitary. Lactating ♀♀ are often caught with young (specimen labels). Vocalizations of this dormouse have frequency components that range from ca. 1 kHz to well into the ultrasonic range above 20 kHz. Most vocalizations (termed 'kecker/shrieks' and recorded from both sexes) seem to occur during agonistic behaviour (Hutterer & Peters 2002). Vocalizations characterized as 'twitters' also recorded from both sexes in non-aggressive close-range situations.

Reproduction and Population Structure Litter-size: 2–4 (Hollister 1919, Hill 1941; specimen labels). Young individuals and lactating ♀♀ found in many months of the year throughout the range; however, paucity of information does not allow any conclusions on reproductive seasons or reproductive strategy. The scattered information includes: Senegal, young in Jul; one young in Aug (Côte d'Ivoire); young in Apr (Benin); pregnant ♀♀ in Nov (Hollister 1919) and Dec, and young in Nov and Apr (Kenya); lactating ♀♀ in Dec and young in Apr (Zimbabwe); lactating ♀♀ in Sep and Oct, and young in Jan (NW Zambia); and young in Oct (Angola) (specimen labels).

Predators, Parasites and Diseases Principal host for the hoplopleurid louse *Schizophthirus graphiuri* (Durden & Musser 1994, Pajot 2000).

Conservation IUCN Category: Least Concern.

Graphiurus lorrainaeus LORRAINE'S AFRICAN DORMOUSE

Fr. Graphiure de Lorrain; Ger. Lorraines Bilch

Graphiurus lorrainaeus Dollman, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 285. Molegbwe, south of the Setema Rapids, Welle (Uele) River, DR Congo.

Taxonomy The named form *lorrainaeus*, originally described as a valid species, has been considered historically as a subspecies or synonym of *G. murinus* (Rosevear 1969, Eisentraut 1973, Genest-Villard 1978a), or as a valid species (Hatt 1940a, Robbins & Schlitter 1981, Holden 1993, 1996, 2005). Populations that are here placed in *G. lorrainaeus* (*haedulus* from Cameroon, *spurrelli* from Ghana) have never been thoroughly analysed and compared to the population of *G. lorrainaeus* from E DR Congo (see Geographic Variation). Future studies may show that one or more populations of what now comprises *G. lorrainaeus* merits recognition as one or more separate valid species. A comparative study of museum specimens and preliminary multivariate analyses (M. E. Holden unpubl.) showed that *G. lorrainaeus* appears to represent a valid species distinct from but closely related to *G. johnstoni*. If future research indicates that the two species are conspecific, *G. lorrainaeus* would become a junior synonym of *G. johnstoni*. Synonyms: *haedulus*, *spurrelli*. Subspecies: none. Chromosome number: $2n = 70$ (an individual from Côte d'Ivoire identified as *G. murinus* (Tranier & Dosso 1979) but probably represents *G. lorrainaeus*).

Description Small dormouse. Dorsal pelage reddish-brown, occasionally sandy or golden-brown. Dorsal pelage soft and short (rump hairs 5–6 mm, guard hairs up to 9 mm). Ventral pelage dark grey washed with cream or ochre, or mostly cream. Dorsal and ventral pelage colours usually not clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask conspicuous in some individuals. Ears brown, short and rounded. Cheeks dark grey washed with cream or ochre, or predominantly cream. Postauricular patches usually not present, but white postauricular patches exhibited by some individuals from Cameroon. Hindfeet usually white with dark metatarsal streak. Tail moderately long (ca. 79% of HB), tail hairs shorter at base (2–3 mm) and longer at tip (up to 21 mm). Tail appears splayed because the hairs project laterally. Tail colour generally matches that of dorsal pelage and is uniform in colour, with sparse or no white hairs, and usually without white tip. Tail may be shorter than normal due to injury, ending in a thick, brush-like tuft of hairs (white in colour). Skull short (24.5 mm), broad (13.8 mm) and moderately vaulted (height of braincase 7.2 mm). Interorbital constriction (4.3 mm) relatively broad. Anterior chamber of auditory bullae markedly less inflated than posterior chambers in some individuals. Rostrum relatively short with short nasal bones (9.1 mm). Anterior palatal foramina comparatively short (mean 2.6 mm) and narrow (mean 1.7 mm), interorbital constriction moderately broad (4.3 mm), palate moderately long (7.8 mm), upper tooththrow moderately long (3.1 mm) and auditory bullae long relative to skull length (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). Nipples: $1 + 1 + 2 = 8$.

Geographic Variation The populations of *G. lorrainaeus* in E DR Congo (*lorrainaeus*) and in S Cameroon (*haedulus*) are smaller than those from Ghana (*spurrelli*). Montane populations in Cameroon (*haedulus*) exhibit morphological and ecological differences compared with *lorrainaeus* and *spurrelli* (see Habitat).

Similar Species (size comparisons refer to mean values only)

Graphiurus christyi. Larger head and body length (mean 97.6 mm), with longer hindfeet (mean 18.0 mm), and longer ears (mean 14.2 mm). Dorsal pelage usually golden-brown or greyish-brown. Skull (28.0 mm) longer, with elongate, higher rostrum and longer nasal bones (10.5 mm); nasal bones and premaxilla extend well beyond incisors from lateral and ventral view. Anterior palatal foramina 3.0 mm long, 2.2 mm wide. Palate absolutely and relatively longer (8.5 mm). Interorbital constriction absolutely broader (4.7 mm), but narrower relative to skull length. Upper tooththrow similar in absolute length (3.2 mm), but relatively shorter. Auditory bullae average slightly longer (7.4 mm), but are relatively shorter (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). Sympatric in NE DR Congo and SW Cameroon. Occurs in NE DR Congo and SW Cameroon.

Graphiurus crassicaudatus. Larger head and body length (mean 92.6 mm). Dorsal pelage similar in colour. Skull longer (26.6 mm) and broader (16.1 mm) with absolutely and relatively broader interorbital constriction (4.9 mm). Anterior palatal foramina absolutely similar in length (2.5 mm) and breadth (1.6 mm), but relatively shorter and narrower. Auditory bullae shorter (6.7 mm) relative to skull length. Palate (9.4 mm) and upper tooththrow (3.8 mm) absolutely and relatively longer (measurements listed are mean values from S Cameroon; M. E. Holden unpubl.). Sympatric at several localities in Liberia, Côte d'Ivoire and SW Cameroon. Occurs in W and WC Africa.

Graphiurus surdus. Larger head and body length (mean 99.0 mm), hindfeet (mean 20.8 mm) longer but relatively similar. Ears similar in absolute length (12.3 mm), but relatively shorter. Dorsal pelage greyish-brown. Skull (27.6 mm) longer; interorbital constriction absolutely broader (4.5 mm), but narrower relative to skull length. Zygomatic arch straight in lateral view (figured in Holden 1996). Palate absolutely and relatively longer (9.3 mm). Anterior palatal foramina similar in length (2.8 mm) and breadth (1.8 mm). Upper tooththrow (3.2 mm) and auditory bullae (7.3 mm) similar in absolute length, but relatively shorter (measurements listed are mean values from Cameroon, Equatorial Guinea and Gabon; Holden 1996). Sympatric in SW Cameroon, Equatorial Guinea and DR Congo. Occurs in C Africa.

Graphiurus johnstoni. Smaller head and body length (mean 74.3 mm), ear (mean 11.8 mm) slightly smaller. Tail relatively longer (68.5 mm) with similar colouration. Dorsal pelage colour similar. Skull slightly shorter (23.6 mm). Rostrum relatively short as in *G. lorrainaeus*, but length of nasal bones absolutely shorter (8.4 mm). Anterior palatal foramina absolutely similar in length (2.7 mm) and breadth (1.7 mm), but relatively longer. Upper tooththrow slightly longer (3.4 mm) and upper premolar broader (1.0 mm). Not sympatric. Occurs in S Malawi.

Graphiurus lorrainaeus

Distribution Endemic to Africa. Rainforest, Guinea Savanna and northern part of Zambezan Woodland BZs, and Rainforest–Savanna Mosaics. Recorded from Guinea to Cameroon, Central African Republic, Congo, E DR Congo, NE Angola and N Zambia; also Bioko I. (see Holden 2005). Not recorded from Togo, Benin and Nigeria west of Niger R. Specimens recorded from Gambia, originally thought to be this species (Schlitter *et al.* 1985) are now considered as *G. kelleni* (Grubb *et al.* 1998, Holden 2005). The western distributional limit for this species is Sierra Leone (Holden 1993, Grubb *et al.* 1998); specimens identified as ‘*Graphiurus murinus*’ (presumably *spurrelli*) from wooded savanna in Senegal (Hubert *et al.* 1973) cannot be substantiated, and are not included here.

Habitat Gallery forests, forest margins, woodland savanna and disturbed areas (including banana, cocoa, palmyra (*Borassus*) and pawpaw farms, and occupied and abandoned buildings) (Hatt 1940a, Heim de Balsac 1967a, Rosevear 1969, Jeffrey 1973, Robbins & Schlitter 1981, Schlitter *et al.* 1985, Grubb *et al.* 1998). In Côte d’Ivoire, Dosso (1975a) noted that the plant *Microdesmis*, commonly found in secondary and disturbed forest, was associated with areas where *G. lorrainaeus* was caught. These dormice were never trapped in, and seemed to avoid, primary forest (Hatt 1940a, Jeffrey 1973). In Cameroon, Eisentraut (1963; and specimen labels) trapped individuals in montane forest at altitudes of 1700–2100 m, but these populations (identified as *haedulus*) may represent a different species (see discussion under Taxonomy).

Abundance Relatively common compared with other forest dormice such as *G. crassicaudatus* and *G. surdus* (Hatt 1940a, Heim de Balsac & Lamotte 1958, Heim de Balsac 1967a, Rosevear 1969, Gautun *et al.* 1986). Comprised 0.77% of muroid and glirid rodents captured at Lamto, Côte d’Ivoire (Dosso 1975a), although in a later survey at Lamto they comprised 7.6% of captures (Traore *et al.* 1980). At Foro, Côte d’Ivoire, comprised 2.1% of rodent captures (Traore *et al.* 1980).

Adaptations Arboreal, although some individuals seem to spend much time on the ground (Rosevear 1969). Nocturnal. Distribution seems to depend on the presence of suitable nesting sites, such as cavities in trees in gallery forest and isolated savanna trees near forest, even in disturbed areas (Verheyen & Verschuren 1966, Rosevear 1969). Many individuals have been caught in or near occupied or abandoned buildings (Verheyen & Verschuren 1966, Rosevear 1969, Jeffrey 1973, Robbins & Schlitter 1981; specimen labels). In C Africa, some individuals have been found nesting in rocky caves (Verheyen & Verschuren 1966). Others were found in abandoned nests of swallows (Hatt 1940a, Verheyen & Verschuren 1966). One such nest (Hatt 1940a) was occupied by an active nest of paper wasps, and the dormice had to crawl upside down on a nearly horizontal stone surface to enter it. Nests have also been found amongst epiphytic ferns (Verheyen & Verschuren 1966) and in a cocoa pod (Schouteden 1946). In Sierra Leone, individuals were caught in spherical nests constructed of pappus. Eisentraut (1963) caught specimens of montane populations in Cameroon in traps set 6–10 m high on large diagonal or horizontal branches near holes in trees; individuals were never trapped on the ground, another indication that this population may represent a different species.

These dormice enter torpor under certain conditions. Lachiver & Petter (1969) found that individuals from Central African Republic became lethargic when experiencing sudden shifts from high to low ambient temperature, or when deprived of food at low temperature. Eisentraut (1962) could not induce torpor in individuals from Cameroon.

Foraging and Food Probably omnivorous, consuming fruit, insects, seeds and nuts. In Liberia, Central African Republic and DR Congo, individuals have been caught in banana plantations, where they reportedly ate the fruit (Hatt 1940a, Chippaux & Pujol 1964, Coe 1975). They have also been caught in areas where palmyra (*Borassus*) (Heim de Balsac 1967a), pawpaw (Jeffrey 1973), *Microdesmis* (Dosso 1975a), cassava, cocoa, oil palm, plantains, *Raphia* and yams are common (specimen labels). The type specimen of *haedulus* was noted to have been ‘caught in bushes eating seeds of *Piper subpellatum*’, a species of pepper (specimen label). Four specimens were taken from a nest containing the remains of several hundred earwigs (Hatt 1940). Verheyen & Verschuren (1966) saw an individual running and jumping after termites, finally capturing them mostly in mid-air.

Social and Reproductive Behaviour Lactating ♀♀ are often caught with young. In DR Congo, one adult ♀ was nesting in an old double nest of a swallow with her three ‘well-grown young’ (Hatt 1940a), indicating that offspring may stay in the nest past weaning. An adult ♂, in captivity, was observed to be very lively and aggressive. It moved its tail up and down with the hairs spread wide, and when excited would chatter ‘gak gak’ repeated four or five times in succession. These dormice reportedly bite ‘furiously’ (H. Lang in Hatt 1940a).

Reproduction and Population Structure Litter-size: 2–7. Mostly 2–4 nestlings or embryos are reported (Hatt 1940a, Eisentraut 1963, Jeffrey 1973). In Côte d’Ivoire, Heim de Balsac (1967a) captured one ♀ with six naked young, and another with a litter of seven (months of capture not given). These two litters are the largest recorded for this species. In Ghana and Cameroon,

pregnant ♀♀ have been collected in Jan, Mar and Jul (Eisentraut 1963, Jeffrey 1973). In Ghana, a lactating ♀ with three placental scars was captured in Nov (Jeffrey 1973).

Predators, Parasites and Diseases Predators include snakes and owls. Remains have been found in the stomach of a green mamba *Dendraspis viridis* (Jeffrey 1973) and in the pellet of a Barn Owl *Tyto alba* (Heim de Balsac & Lamotte 1958).

Conservation IUCN Category: Least Concern.

Graphiurus microtis NOACK'S AFRICAN DORMOUSE

Fr. Graphiure de Noack; Ger. Noack's Bilch

Graphiurus microtis (Noack, 1887). Zoologische Jahrbücher 2: 248. Qua Mpala, Marungu, DR Congo.

Taxonomy Originally described in genus *Eliomys*. The type specimen of *G. microtis* has been lost, but Noack's (1887) figure depicts a dormouse whose skull morphology agrees with specimens of *G. microtis* from regions near the type locality (Holden 2005). The taxon *microtis* has historically been listed as a synonym or valid subspecies of *G. murinus* (Allen 1939, Ellerman *et al.* 1953, Genest-Villard 1978a). Genest-Villard (1978a) separated what she considered to be the 'savanna subspecies' of *G. murinus* from the 'forest subspecies', and considered *G. m. microtis* to be one of several valid savanna subspecies. Ansell (1989a) agreed, but considered that the three savanna subspecies comprised a single valid species, *G. microtis*, on the basis of morphological and ecological differences, a position endorsed by Holden (1993, 2005).

Holden (1996) summarized the historical taxonomic arrangements of *G. murinus* and other species of *Graphiurus*. Many of the 76 specific and subspecific names proposed for African Dormice are synonyms of *G. murinus* or *G. microtis*. Because *G. microtis* is now recognized as a valid species (Ansell & Dowsett 1988, Ansell 1989a, Holden 1993, 2005), synonyms associated with it have traditionally been listed as synonyms of *G. murinus*. Holden (1993) did not separate the synonyms associated with *G. murinus* and *G. microtis*, but the taxonomy presented here results from further examination of specimens, data and multivariate analyses (M. E. Holden unpubl.). Historically, many authors have not recognized *G. microtis* as a valid species, and the data given in their papers are thus composite for both species; when such publications are cited here, only the sections relevant to *G. microtis* as outlined in this account are pertinent. The species requires taxonomic revision; significant geographic variation exists, and it is likely that two or more separate species are contained within *G. microtis*. Synonyms: *albolineata*, *butleri*, *etoschae*, *griselda*, *littoralis*, *marrensis*, *?orobinus*, *pretoriae*, *schneideri*, *smithii*, *streeteri*, *sudanensis*, *tzaneenensis*, *vandami*, *woosnami* (Holden 2005). Subspecies: none. Chromosome number: 2n = 46 (Transvaal, South Africa; D. N. MacFadyen pers. comm.; see species profile for *G. murinus* for discussion of karyotypes).

Description Small dormouse. Dorsal pelage various shades of brown, beige or grey, sometimes with golden or reddish hue, with

darkening towards the mid-line of head and back in some individuals. Dorsal pelage usually sleek, but moderately thick in some populations (rump hairs 6–8 mm, guard hairs up to 13 mm). Ventral pelage usually white or cream, slightly or moderately suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour usually matches that of dorsal pelage, sometimes becoming paler towards muzzle. Eyes large; eye-mask conspicuous. Ears brown, medium or large, rounded. Cheeks cream or white, forming part of a pale lateral stripe that extends from cheeks to shoulders. Cream or white postauricular patches usually present. Hindfeet white, or white with dark metatarsal streak. Tail moderately long (ca. 76% of HB), hairs shorter at base (5–8 mm) and longer at tip (up to 26 mm). Tail colour generally matches that of dorsal pelage. White hairs are usually mixed throughout tail; tip white. Skull moderately long (27.4 mm) with slightly to moderately vaulted braincase (height of braincase 7.5 mm), and relatively long anterior palatal foramina (3.4 mm). Anterior palatal foramina moderately long (mean 3.4 mm) and wide (mean 2.1 mm). Interorbital constriction narrow (3.9 mm) and auditory bullae usually long (8.1 mm) and inflated relative to skull length. Nipples: 1 + 1 + 2 = 8.

Geographic Variation Certain populations of this dormouse exhibit variations in the colour of the dorsal pelage and in skull morphologies that are consistent within these populations; e.g. in C Botswana, dorsal pelage colour is ash-grey and skulls tend to be long and comparatively flat, with a narrow interorbital constriction. In nearby Namibia, dorsal pelage colour is also grey, but skulls are shorter and more vaulted, with a broader interorbital constriction. Other populations, e.g. certain populations in Uganda and Sudan, have sandy- to medium-brown dorsal pelage, a long and comparatively vaulted skull with long anterior palatal foramina, broad interorbital constriction, and greatly inflated auditory bullae. Differences like these are found throughout the range of *G. microtis*. Some populations have such distinctive morphologies that future studies may show that one or more of them is a separate valid species.

Similar Species (size comparisons refer to mean values only)

Graphiurus angolensis: Similar head and body length (mean 98.8 mm).

Tail (mean 79.2 mm) and hindfeet (mean 18.4 mm) absolutely and relatively longer. Dorsal pelage sometimes similar in colour. Skull similar in length (28.2 mm), but slightly broader (15.5 mm) and more vaulted (height of braincase 7.9 mm). Auditory bullae markedly longer (9.0 mm) and more inflated relative to skull length (measurements listed are mean values from Kabompo and Zambezi [formerly Balovale], Zambia; M. E. Holden unpubl.). Parapatric in NW Zambia (Ansell 1978). Occurs in Angola and NW Zambia.

Graphiurus johnstoni: Smaller head and body length (mean 74.3 mm).

Tail relatively longer (mean 68.5 mm). Dorsal pelage colour sometimes similar, tail colour usually uniform and without white tip. Skull shorter (23.6 mm) and narrower (13.9 mm). Interorbital constriction (4.0 mm) similar in breadth, but relatively broader. Anterior palatal foramina absolutely and relatively shorter. Upper tooththrow (3.4 mm) longer and auditory bullae (6.8 mm) shorter both absolutely and relative to skull length (measurements listed are mean values from S Malawi; M. E. Holden unpubl.). Sympatric in Thyolo, Malawi, but probably not syntopic. Currently known to occur only in S Malawi.

Graphiurus kelleni: Smaller head and body length (mean 82.4 mm); ears shorter (mean 14.8 mm). Dorsal pelage colour sometimes similar. Tail usually more uniform in colour, with inconspicuous white tip. Skull shorter (24.0 mm) and narrower (13.5 mm). Breadth of interorbital constriction (4.0 mm) and length of upper tooththrow (2.9 mm) absolutely similar, so relatively larger in *G. kelleni*. Auditory bullae somewhat shorter (7.8 mm) both absolutely and relative to skull length (measurements listed are mean values from Zambezi, Zambia; M. E. Holden unpubl.). Sympatric in savannas throughout much of sub-Saharan Africa.

Graphiurus murinus: Similar head and body length (mean 91.5 mm). Hindfeet (18.5 mm) longer, and ears (13.3 mm) shorter. Dorsal pelage colour sometimes similar. Postauricular patches inconspicuous or not present. Ventral pelage colour usually greyer and not clearly delineated from dorsal pelage. Hindfeet usually have dark metatarsal streak. Tail usually uniform in colour, white tip inconspicuous or absent. Skull similar in length (26.4 mm), but slightly narrower (14.2 mm) and more vaulted (height of braincase 8.1 mm). Anterior palatal foramina absolutely slightly shorter (3.1 mm), but relatively shorter. Interorbital constriction broader (4.5 mm), and auditory bullae shorter (7.1 mm) and less inflated relative to skull length (measurements listed are mean values from Mt Kenya; M. E. Holden unpubl.). Not sympatric. Occurs in forests throughout much of sub-Saharan Africa.

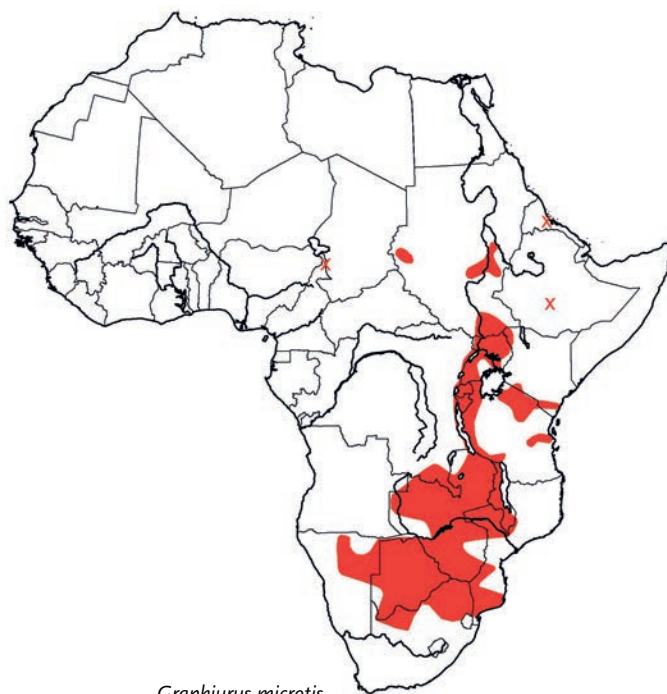

Graphiurus platyops: Larger head and body length (mean HB: 107.1). Tail (mean 78.7 mm) absolutely longer, but relatively shorter. Hindfeet (21.1 mm) longer, and ears (15.2 mm) shorter, both absolutely and relatively. Dorsal pelage grey to greyish-brown. Inconspicuous white postauricular patches sometimes present. Tail tip white. Skull longer (30.4 mm) and broader (17.1 mm). Height of braincase (7.8 mm) similar, so relatively flattened in *G. platyops*. Interorbital constriction (4.8 mm) absolutely and relatively broader. Anterior palatal foramina absolutely similar in length (3.2 mm), but relatively shorter. Upper tooththrow

(3.1 mm) and auditory bullae (8.4 mm) similar to slightly longer, so are relatively shorter (measurements listed are mean values from Zimbabwe and NE South Africa populations; M. E. Holden unpubl.). Generally sympatric throughout range of *G. platyops*, but seem to be segregated by habitat, and are probably not syntopic. Occurs in rocky habitats in eastern and south-eastern Africa.

Graphiurus rupicola: Slightly larger head and body length (mean 110 mm). Tail (104.2 mm). Hindfeet (21.5 mm) absolutely and relatively longer. Dorsal pelage colour sometimes similar in colour, especially in animals from Namibia. Small, cream supra-auricular patches and faint white postauricular patches present. Tail tip white. Skull markedly longer (31.3 mm) and most skull measurements are accordingly larger. Upper tooththrow (3.4 mm) absolutely longer, but relatively similar. Upper premolar (0.9 mm) absolutely slightly broader, but relatively narrower. Anterior palatal foramina absolutely similar in length (3.4 mm), but relatively shorter. Auditory bullae (9.5 mm) longer both absolutely and relative to skull length (measurements listed are mean values from Namibia; M. E. Holden unpubl.). Sympatric near Okahandja, Namibia. Occurs in rocky habitats in Angola, Namibia and NW South Africa.

Distribution Endemic to Africa. Widespread in Zambezan Woodland BZ, with extensions into parts of Eastern Rainforest–Savanna Mosaic, Guinea Savanna and Sudan Savanna BZs on the eastern side of the continent. Recorded from savannas in Chad, Sudan, Eritrea and Ethiopia south to Namibia and NE South Africa (Holden 2005). Late Quaternary fossils of *G. microtis* have been recorded from C Zambia (Avery 1996).

Habitat Woodland savanna, riverine woodland, rocky areas including caves, disturbed areas, and human dwellings. These dormice have been captured in or near aloes, willows, upaca trees

Graphiurus microtis

(*Upaca kirkiana*), thorn trees (*Acacia* sp.), camel thorn (*Acacia erioloba* (*giraffae*)), Zambeian teak or mukusi (*Baikiaea* sp.), mopane (*Colophospermum mopane*), leadwood (*Conbreum imberbe*), seringa (*Burkea* sp.), palm (*Hyphaene* sp.) and buffalo thorn (*Ziziphus mucronata*) (Shortridge 1934, Misonne 1965a, Misonne & Verschuren 1966, Smithers 1971, Wilson 1975, Smithers & Wilson 1979, Ansell & Dowsett 1988; specimen labels). They have been captured in tall grass near shrubs and trees, and in piles of debris deposited by high floods near seasonally dry rivers (Smithers 1983). Individuals have been observed on a vertical rock face at the entrance of a cave situated on a rocky hillside (Ansell 1974), and captured among rocks in or near caves (Roberts 1917, Misonne 1965a, Misonne & Verschuren 1966). Common also in disturbed areas, including buildings, fields, gardens and near rubbish dumps (Wilson 1975, Smithers & Lobão Tello 1976, Smithers & Wilson 1979, Ansell & Dowsett 1988, Taylor *et al.* 1994). When evaluating the range of microhabitats tolerated by these dormice, it is important to consider that more than one valid species is probably contained within *G. microtis* (see Taxonomy).

Abundance Common. Although published faunal surveys have not estimated population densities (due to the commonly mistaken inclusion of this species in *G. murinus*), the large number of museum specimens, and notes written on specimen labels, indicate that it is common throughout much of its range. In Malawi, Ansell & Dowsett (1988) found it to be the most frequently encountered dormouse, and stated that it is widely distributed.

Adaptations Primarily arboreal, partly terrestrial (Smithers & Wilson 1979, Smithers 1983). Nocturnal (Smithers 1971, 1983, Wilson 1975, Smithers & Wilson 1979). These dormice frequently nest in crevices under bark, or in holes in savanna trees (Shortridge 1934, Smithers & Lobão Tello 1976, Smithers 1983). The entrance to most nesting holes is circular, and is commonly situated 1–3 m above ground, although some have been found at heights of up to 6 m (Shortridge 1934; specimen labels). Nests are composed of soft plant material or grass, and sometimes feathers (Roberts 1951; specimen labels). They also nest in rocky habitats. One individual was observed at a cave entrance easily negotiating a vertical rock face (Ansell 1974), another was captured among rocks near a cave (Misonne 1965a). Several individuals nested in aloes in rocky terrain (Smithers & Lobão Tello 1976). They also utilize the nests of birds; one individual made its nest inside the nest of a swallow *Hirundo abyssinica* under a rock; the dormouse's nest contained feathers, wood debris, grass and scales from a snake (Misonne 1965a). Several adults and young have been found in nests of various species of weaver-birds (Roberts 1951). Nests may also be built in huts and houses, often in thatched roofs, sometimes in pantries or even in switch boxes of water pumps or transformers where they have caused short circuits in electrical supplies (Wilson 1975, Smithers & Lobão Tello 1976, Smithers 1983, specimen labels).

Foraging and Food Probably omnivorous, consuming fruit, insects, seeds, nuts and occasionally small vertebrates. Stomach contents have included dry outer skins of buffalo thorn fruit *Ziziphus mucronata*, seeds of *Acacia* sp., insects – including large moths, rose beetles, millipedes *Doratogonus flavifilis*, but not blister beetles nor Hemiptera (Misonne 1965a, Smithers 1971, 1983, Smithers & Wilson 1979, Pienaar *et al.* 1980). The stomach of one individual contained the remnants of a small bird (specimen label).

Social and Reproductive Behaviour Little information. Males are apparently solitary. Lactating ♀♀ are often caught with young.

Reproduction and Population Structure Litter-size: 3–7 (specimen labels). Most often 3–4 embryos or nestlings are reported (Ansell 1974, Wilson 1975, Smithers & Wilson 1979, Sheppe & Haas 1981, specimen labels). In Uganda, a pregnant ♀ was captured in Nov, and two lactating ♀♀ were captured in Aug. In Malawi, a pregnant ♀ was collected in Oct (Ansell 1974). In Botswana, a pregnant ♀ was obtained in Apr (Sheppe & Haas 1981). In Zimbabwe, pregnant ♀♀ have been collected in Feb, Apr, Jun, Nov and Dec (Wilson 1975, Smithers & Wilson 1979).

Predators, Parasites and Diseases One individual was found in the stomach of a mamba *Dendroaspis* sp. (specimen label). Close to 20 individuals were identified in owl pellets collected in Kruger N. P., South Africa (M. E. Holden unpubl.). These dormice are the type and a principal host for the trypanosome *Trypanosoma graphiuri* (Dekeyser 1955). They may host the same ectoparasites as *G. murinus* (see species profile).

Conservation IUCN Category: Least Concern.

Mary Ellen Holden

Graphiurus monardi MONARD'S AFRICAN DORMOUSE

Fr. Graphiure de Monard; Ger. Monards Bilch

Graphiurus monardi (St Leger, 1936). Ann. Mag. Nat. Hist., ser. 10, 17: 465. Kioko, 15 km above Dala, Tyihumbwe (Chiumbe) River, Angola. 1250 m (see Hill & Carter 1941).

Taxonomy Originally described in the genus *Claviglis*. Allen (1939) included *monardi* as a subspecies of *nagtglasii*, and Genest-Villard (1978a) followed this arrangement. Ellerman *et al.* (1953), Robbins & Schlitter (1981) and Holden (1993, 2005) agree that *monardi* has no close affinity with *G. nagtglasii*. Genest-Villard (1978a) included *schoutedeni* as a synonym of *G. platyops*, but Ansell (1989a) correctly arranged it as a synonym of *G. monardi*. Synonyms: *schoutedeni* (Ansell 1989a). Subspecies: none. Chromosome number: not known.

Description Large dormouse. Dorsal pelage yellowish-brown, darkening towards mid-line due to a higher density of guard hairs in that region. Dorsal pelage sleek and long (rump hairs 11–13 mm, guard hairs up to 17 mm), with many conspicuous dark brown guard hairs projecting beyond the fur. Ventral pelage cream, sometimes lightly suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask usually conspicuous. Ears brown, relatively small, rounded. Cheeks cream. Cream postauricular patches sometimes present. Hindfeet cream, sometimes with a thin, dark metatarsal streak. Tail moderately long (ca. 81% of HB), hairs shorter at base (6–9 mm) and longer at tip (up to 33 mm). Dorsal tail colour generally matches that of dorsal pelage, but ventral tail colour paler brown. Many white hairs are mixed throughout tail; tip white or cream. Skull long (34.1 mm) and vaulted (height of braincase 9.4 mm). Interorbital constriction narrow (mean 5.0 mm), anterior palatal foramina very long (4.1 mm) and wide (2.6 mm), and palate short (mean 10.7 mm) relative to skull length. Upper toothrow moderately broad as exhibited by medium breadth of upper premolar (mean 1.1 mm). Auditory bullae (mean 10.3 mm) absolutely and relatively long and inflated Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus nagtglasii: This species is strikingly unlike *G. monardi*, but a comparison is given here due to previous inclusion of *monardi* in *G. nagtglasii*. Similar head and body length (mean 138.5 mm); most specimens of *G. monardi* have no data on head and body measurements, but based on specimen comparisons the size range of the two species is similar. Ear (mean 18.1 mm) and hindfoot (mean 26.5 mm) are absolutely and relatively longer. Dorsal pelage shorter and woolly, with inconspicuous guard hairs. Skull longer (mean 36.8 mm) with absolutely and relatively longer palate (mean 13.0 mm). Anterior palatal foramina shorter (3.7 mm) and narrower (2.3 mm) relative to skull length. Auditory bullae absolutely and relatively shorter (mean 7.9 mm) and much less inflated. Not sympatric. *Graphiurus nagtglasii* occurs in West Africa from Sierra Leone to Gabon.

Graphiurus monardi

Distribution Endemic to Africa. Zambezan Woodland BZ. Known from only seven localities in NE Angola, S DR Congo and NW Zambia.

Habitat Central African savanna. No specific habitat information has been recorded for this dormouse. All specimens, except one from Katanga (DR Congo), have been taken on plateaux in wetter Miombo woodland. St Leger (1936) gives anecdotal information obtained from Dr Monard that this dormouse occurs in forest, as well as in cultivated fields and houses. Another species, *G. angolensis*, is also found in this region, and is known to frequent vacant and occupied buildings. It is likely that some, if not all, of the reports of this species in cultivated fields and buildings are attributable to *G. angolensis*.

Abundance Little information. Only about a dozen museum specimens exist. Judging from the large numbers of specimens of dormice and other animals collected at some of the same localities, *G. monardi* appears to be rare.

Remarks Probably predominantly arboreal. Hayman (1963b) includes photographs of a live animal climbing on a branch.

Conservation IUCN Category: Data Deficient.

Mary Ellen Holden

Graphiurus murinus FOREST AFRICAN DORMOUSE

Fr. Graphiure murin (Lérot de savanne); Ger. Busch-Bilch

Graphiurus murinus (Desmarest, 1822). Mammalogie. In: Encyclop. Méth., 2 (Suppl.): 542. Cape of Good Hope, South Africa.

Taxonomy Originally described in genus *Myoxus*. Many of the 76 scientific names proposed for African Dormice are synonyms of *G. murinus* (which usually inhabits forests) or *G. microtis* (which usually inhabits savannas) (see Holden 1996). Historically, many authors have not recognized *G. microtis* as a valid species, and the data given in their papers are thus composite for both species; when such publications are cited here, only the sections relevant to *G. murinus* as outlined in this account are pertinent. The species needs taxonomic revision, requiring comprehensive comparisons with *G. lorrainus*, *G. johnstoni*, *G. microtis* and *G. christyi* (Holden 2005). Significant morphological geographic variation exists, and it is likely that two or more separate species are contained within *G. murinus*. Because the definition of this species is so uncertain, information on abundance, distribution and biology may be applicable to other species, as yet undescribed. Synonyms: *alticola*, *cineraceus*, *cinerascens*, *collaris*, *erythrobrachus*, *griseus*, *isolatus*, *johnstoni* Heller, 1912 (not Thomas, 1898), *lalandianus*, *raptor*, *saturatus*, *selindensis*, *soleatus*, *?subrufus*, *vulcanicus*, *zuluensis*. Subspecies: none. Chromosome number: 2n = 46 (Natal, South Africa, D. N. MacFadyen pers. comm.; Hobbiton, South Africa, Kryštufek *et al.* 2004). Three different karyotypes were reported in the *G. murinus* species group in southern Africa (Dippenaar *et al.* 1983); however, *G. microtis* may have been included in this sample.

Description Small dormouse. Dorsal pelage various shades of golden- or greyish-brown, sometimes with reddish or coppery hue, with darkening of pelage towards the mid-line of head and back in some individuals. Dorsal pelage soft, silky, sometimes thick (rump hairs 7–8 mm, guard hairs up to 13 mm). Ventral pelage grey, lightly suffused with white or cream. Dorsal and ventral pelage colours usually not clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask conspicuous in some populations. Ears brown, medium-sized, rounded. Cheeks cream or white. Postauricular patches usually not present. Hindfeet usually white with dark metatarsal streak. Tail moderately long (ca. 84% of HB), tail hairs shorter at base (2–4 mm) and longer at tip (up to 21 mm). Tail colour generally uniform, matching that of dorsal pelage. White hairs are sometimes mixed inconspicuously throughout tail in some populations, tip usually not white although some populations exhibit very faint white tip. Skull moderately long (26.4 mm) with moderately vaulted braincase (height of braincase 8.1 mm). Anterior palatal foramina of moderate length (3.1 mm) and width (1.9 mm); anterior portion often narrower anteriorly, resulting in tear-drop

shape. Palate moderately long (4.4 mm) and auditory bullae usually short (7.1 mm) and uninflated or moderately inflated relative to skull length. Nipples: 1 + 1 + 2 = 8.

Geographic Variation As with *G. microtis*, significant variation in external and skull morphology exists, and these differences are consistent within certain populations. Kryštufek *et al.* (2004) found that individuals from riverine forest near Grahamstown, South Africa, were significantly larger, and differed significantly in several cranial dimensions and proportions (weight, head and body, ear and length of PM⁴) than individuals from Afromontane forest at Hobbiton, South Africa (Kryštufek *et al.* 2004). Individuals from Ukinga Highlands, Tanzania, have smaller, broader skulls, with broader interorbital constriction and wider cheekteeth than individuals from nearby Uzungwa Mts and Rungwe Mts, Tanzania. Differences such as these are found throughout the range of *G. murinus*. Some populations have distinctive morphologies, and future studies may show that one (or more) of these populations is a separate species.

Similar Species (size comparisons refer to mean values only)

Graphiurus microtis. Similar head and body length (mean 98.8 mm). Hindfeet (mean 16.9 mm) shorter, ears (mean 15.5 mm) longer. Dorsal pelage colour similar to *G. murinus* in some populations. Postauricular patches often conspicuous. Ventral pelage colour usually paler and well delineated from dorsal pelage. Hindfeet usually white or cream. Tail usually with conspicuous white tip. Skull similar in length (27.4 mm), slightly broader (15.0 mm) and braincase less vaulted (height of braincase 7.5 mm). Anterior palatal foramina absolutely only slightly longer (3.4 mm), but relatively noticeably longer. Interorbital constriction narrower (3.9 mm) and auditory bullae longer (8.1 mm) and more inflated relative to skull length (measurements listed are mean values from Zimbabwe; M. E. Holden unpubl.). Not sympatric. Occurs in savannas throughout much of sub-Saharan Africa.

Graphiurus kelleni. Smaller head and body length (mean 82.4 mm). Hindfeet (mean 16.0 mm) shorter, ears (mean 14.8 mm) absolutely and relatively larger. Dorsal pelage colour similar to *G. murinus* in some populations. Skull shorter (24.0 mm), narrower (13.5 mm) and braincase less vaulted (height of braincase 7.0 mm). Anterior palatal foramina 2.9 mm long, 1.7 mm wide. Interorbital constriction slightly narrower (4.0 mm), and auditory bullae longer (7.8 mm) and much more inflated relative to skull length (measurements listed are mean values from Zambia; M.

Graphiurus murinus

E. Holden unpubl.). Generally not sympatric, although they have been captured in close proximity at several localities in Kenya. Occurs in savannas throughout much of sub-Saharan Africa.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ in eastern and southern Africa, Highveld BZ, and Coastal Forest Mosaic BZ in southern part of range. Recorded from Ethiopia, Kenya, Uganda, Rwanda, Burundi (and possibly extreme NE DR Congo), Tanzania, N Malawi, Zimbabwe, South Africa, Swaziland and Lesotho (Holden 2005).

Habitat Primarily a forest species. Recorded mostly at altitudes of 1000–4100 m, and occasionally at sea level in coastal forests. Very adaptable and found in many types of forest (Afromontane, plateau, riverine, coastal). Less commonly recorded from montane grassland with rocks, giant groundsel, or trees. Rarely recorded from dry scrub or thicket. When evaluating the range of microhabitats tolerated by these dormice, it is important to consider that more than one valid species is probably contained within *G. murinus* (see Taxonomy). For example, at Grahamstown, South Africa, these dormice were trapped only in riverine forest and not in nearby dry thicket (B. Kryštufek pers. comm.), whereas at other South African localities individuals were captured in dry thicket and among rocks (Taylor 1998). It may be that individuals trapped in habitats other than forest are members of populations that will later be considered separate species.

Abundance Common in some regions, uncommon in others. In Giant's Castle Game Reserve, South Africa, relative abundance (as assessed by trap success) was 0.3% in grouped tree woodland, 0.8% in scrub, 3.8% in forest, 0.6% in temperate grassland boulder bed and 0.4% in temperate grassland (Rowe-Rowe & Meester 1982a). The species is fairly common and widespread in SE South Africa from Western Cape Province to Mpumalanga and Limpopo

Provinces, South Africa (Swanepoel 1988, Lynch 1983, 1989, Taylor 1998), but uncommon in Lesotho (Lynch 1994). Uncommon in four out of six montane forests in the Eastern Arc Mts, Tanzania (South Pare, West Usambara, East Usambara and Uluguru), and seemingly absent in two forests (Nguru and Udzungwa) (Stanley *et al.* 1998a, b); although Allen & Loveridge (1933) reported one individual from Udzungwa. At Chome Forest Reserve, Tanzania, comprised only 0.6% of small rodents (1 of 165) (Stanley *et al.* 1998a). Trap success (and assessment of abundance) is probably higher for traps set above ground than on the ground e.g. in Afromontane forest in South Africa, trap success was 2.3% above ground and 0.1% on the ground, and most individuals (94.5%) were captured in traps placed more than 0.5 m above ground (Kryštufek *et al.* 2004). Most published information derives from South African populations; more information is needed from populations throughout the range of the species to generally characterize its abundance.

Adaptations Primarily arboreal, partly terrestrial; some populations rupicolous. Frequently nests in holes and crevices in forest trees (Roberts 1951; specimen labels). Nests have also been found among epiphytic ferns and mosses of giant forest trees (Allen & Loveridge 1933), in beehives (Kingdon 1974), in swallows' nests, and less commonly, in human dwellings. Nests are often composed of strips of grass, bark and other material, which is finely shredded and formed into a round ball (Roberts 1951). A nest in NE South Africa was constructed of moss and lined with sheep's wool (specimen label). On Mt Kilimanjaro, Tanzania, a globular nest was composed of grass and slips of banana fronds, and lined with fine grass; it was about 13 cm in diameter, with a hole in its side, and was situated about 1.5 m above ground in a bush (specimen label).

Under certain conditions, will enter torpor (as do many species of glirids). If experimentally deprived of food at $T_a = 25^\circ\text{C}$, individuals initially decreased activity, but remained euthermic. At $T_a = 10^\circ\text{C}$, when deprived of food, the same individuals entered torpor with greater frequency during the day (Webb & Skinner 1996b). Cold temperatures (10°C) and simulated winter photoperiod (10 hours light, 14 hours dark) also induced torpor; these periods of torpor exceeded 24 hours, suggesting hibernation or deep torpor occurs under these conditions (Ellison & Skinner 1991).

The digestive system indicates a diet of mainly protein (see also below). Compared with 18 spp. of other rodents (mostly murids), the alimentary canal is short in relation to head and body length (3.7 times HB, cf. 4.8–5.6 for herbivores), the small intestine is relatively short and the large intestine is relatively long in relation to total hindgut length; the caecum is absent (the only species of those studied without a caecum) and there are no spiral folds in the large intestine (cf. all other 18 spp. except *Cryptomys hottentotus*). Most of these characters are primitive and indicative of a nutritious diet (Perrin & Curtis 1980).

Foraging and Food Omnivorous, predominantly insectivorous and carnivorous. Stomach contents have included insects and other invertebrates, seeds, leaves, stems, fruit and occasionally small vertebrates (Kingdon 1974, Perrin & Curtis 1980, Rowe-Rowe 1986, Wirminghaus & Perrin 1992, Taylor 1998; specimen labels). In KwaZulu–Natal, South Africa, most stomachs contained seeds, and all contained arthropods ($n = 11$; Rowe-Rowe 1986). In another study

in KwaZulu–Natal, South Africa, stomachs contained invertebrates (88.8%), fruits (11.04%), leaves and stems (0.16%), and flowers (0%); this population was thus predominantly insectivorous with more than 80% of the diet in any month comprising invertebrates ($n = 23$; Wirminghaus & Perrin 1992). One individual found in a beehive (Duff-MacKay 1965, quoted by Kingdon 1974) was extremely fat, and its stomach contained a brown sludge with white specks – presumably honey and wax.

Social and Reproductive Behaviour Little information. Lactating ♀♀ often caught with young. Allen & Loveridge (1933) observed subadult nestlings following an adult ♀ (up to eight individuals) as they climbed and leapt across tree branches. In two separate instances, adult ♀♀ were captured with two subadult ♂♂, indicating that offspring may stay in the nest past weaning (Allen & Loveridge 1933; specimen label).

Reproduction and Population Structure Litter-size: 1–5. Most often 3–4 embryos or nestlings are reported (Hollister 1919, Ansell 1974, De Graaff 1981; specimen labels). In Kenya, pregnant ♀♀ were collected in Sep and Nov (specimen labels). In Zambia, a pregnant ♀ was captured in Jul (Ansell 1974). In South Africa, ♀♀ exhibiting placental scars were captured in Feb, and pregnant ♀♀ were collected in Oct, Dec and Feb (Lynch 1989; specimen labels). Taylor (1998) suggests that this species may breed mostly during summer in KwaZulu–Natal, South Africa. No information on gestation and development of young. Sex ratio has been found to be female-biased in some southern African populations (De Graaff 1981, Smithers 1983).

Predators, Parasites and Diseases No information on predators. Most authors have included *G. microtis* as a synonym of

G. murinus, and therefore the ectoparasites listed here could have been collected from either species. Ectoparasites include three families of mites (Laelaptidae [1 sp.], Erynetidae [1 sp.] and Trombiculidae [8 spp.]), four families of fleas (Ceratomyzidae [1 sp.], Chimaeropsyllidae [1 sp.], Hystricopsyllidae [7 spp.] and Pulicidae [5 spp.]), and the rhipicephalid tick *Rhipicephalus simus* (De Graaff 1981). Type (and principal) host for the hoplopleurid louse *Schizophthirus graphiuri* (Durden & Musser 1994, Pajot 2000).

Conservation IUCN Category: Least Concern.

Further sampling is required to assess conservation status throughout geographic range; some historically recorded populations may be threatened or even extinct (e.g. the population in the Udzungwe Mts, Tanzania).

Graphiurus nagtglasii NAGTGLAS'S AFRICAN DORMOUSE

Fr. Graphiure de Nagtglas (formerly Graphiure de Huet); Ger. Nagtglas Bilch

Graphiurus nagtglasii Jentink, 1888. Notes from the Leyden Museum 10: 38–41. Hill Town, Du Queah River, Liberia (restricted locality).

Taxonomy Most previous publications on dormice in West Africa have referred to this species as *G. hueti* (Huet's African Dormouse). Although originally described in genus *Graphiurus*, it was later placed in its own genus, *Aethoglis* (Allen 1936; see profile Genus *Graphiurus*). Grubb & Ansell (1996) recommended applying the name *G. nagtglasii* to the large West African dormouse, traditionally known as *G. hueti*, because of the dubious nature of the type locality of *G. hueti* given by de Rochebrune (1883), the lack of an available or likely holotype for *G. hueti*, and the existence of a holotype for *nagtglasii*. The animal used by de Rochebrune as a model to figure *G. hueti* is probably from Gabon, not Senegal (the type locality of *G. hueti*). Jentink (1888, and on his specimen labels) designated a series of five syntypes representing *G. nagtglasii* from Ghana and Liberia, and listed what are presumed to be the type localities as the Du Queah and Farmington rivers for the three Liberian specimens. As Rosevear (1969) noted, Jentink based his description on (and gave measurements for) an adult ♂ in alcohol that he considered typical of the species. Allen (1939) and Genest-

Villard (1978a) included *G. monardi* as a subspecies of *G. hueti* (now *G. nagtglasii*), but Ellerman *et al.* (1953), Ansell (1978), Robbins & Schlitter (1981) and Holden (1993, 2005) observed that *G. monardi* is clearly distinct from and probably not closely related to *G. nagtglasii*. Synonyms: *argenteus*, *hueti* (see Allen 1939, Grubb & Ansell 1996). Subspecies: none. Chromosome number: $2n = 40$ (Tranier & Dosso 1979).

Description Large dormouse. Dorsal pelage brown, greyish-brown, or rufous. Dorsal pelage soft, woolly, dense and short (rump hairs 5–7 mm, guard hairs up to 12 mm). Ventral pelage dark grey washed with ochre, cream or white. Dorsal and ventral pelage colours not clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask usually conspicuous. Ears brown, medium-length, narrow and pointed. Cheeks greyish-white or ochraceous-white. Postauricular patches not present. Hindfeet brown, or white with dark metatarsal streak. Tail moderately long (ca. 76% of HB), tail hairs shorter at base (14–18 mm) and longer at tip (up

to 37 mm). Tail colour generally matches that of dorsal pelage, but has variegated frosted appearance. A few white hairs are occasionally mixed throughout tail; tip not white. Tail distichous underneath, and often nearly naked along mid-ventral line. Skull large, vaulted (height of braincase 10.2 mm) and somewhat broad (20.7 mm) relative to skull length. Anterior chamber of auditory bullae usually markedly less inflated than the posterior chambers. Interorbital constriction (5.5 mm) relatively narrow. Palate (13.0 mm) and upper toothrow (5.1 mm) relatively long, and wide as exhibited by breadth of upper premolar (1.5 mm). Anterior palatal foramina absolutely somewhat long (mean 3.7 mm) but relatively short. Auditory bullae short (7.9 mm) and uninflated relative to skull length (measurements listed are mean values from Ghana; M. E. Holden unpubl.). Nipples: $1 + 1 + 2 = 8$.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus monardi. This species is not at all similar to *G. nagtglasii*, but a comparison is given here due to previous inclusion of *G. monardi* in *G. nagtglasii*. Probably similar head and body length (mean 160 mm). (Only one adult specimen of *G. monardi* has information on head and body length associated with it; however, head and body length appears to be similar for other specimens.) Ear (15.5 mm) and hindfeet (21.9 mm) are shorter both absolutely and relative to skull length. Dorsal pelage long, straight and silky, with many conspicuous dark brown guard hairs. Skull shorter (34.1 mm) with absolutely and relatively shorter palate (10.7 mm). Anterior palatal foramina longer (4.1 mm), both absolutely and relative to skull length. Auditory bullae (10.3 mm) absolutely and relatively longer, and much more inflated (measurements listed are mean values from NE Angola, S DR Congo and NW Zambia populations; M. E. Holden unpubl.). Not sympatric. Occurs in S DR Congo, NE Angola and NW Zambia.

Graphiurus nagtglasii

Distribution Endemic to West Africa. Rainforest BZ (Western and West Central Regions) and Northern Rainforest–Savanna Mosaic. Recorded in or near rainforest from S Sierra Leone to Cameroon (excluding Benin), SW Central African Republic and Gabon. The southern distributional limit of this species is not known, as the Gabon specimen has no specific locality. Although de Rochebrune (1883) listed the type locality of *G. hueti* as Senegal, and reported it from neighbouring Gambia, the occurrence of the species has never been substantiated in these countries (Grubb & Ansell 1996).

Habitat Recorded in rainforest, secondary forest, abandoned farmlands, in cocoa plantations and other farms in forested areas (Rosevear 1969, Happold 1987, as *G. hueti* specimen labels). Most museum specimens were collected from hollow trees, one from an old hollow banana stem, and several from banana groves within cocoa plantations (Jeffrey 1973). They are often caught by farmers preparing new farms from secondary bush or forest (Jeffrey 1973). Several individuals were trapped on vines in secondary forest near hollow trees (Robbins & Schlitter 1981).

Abundance Rosevear (1969) stated that these dormice are fairly common and widespread throughout the West African rainforest. In Côte d'Ivoire, Heim de Balsac (1967a) found them to be fairly common in Lamto. In contrast, Dosso (1975a) did not trap this dormouse during his faunal study at Adiopodoumé, Côte d'Ivoire. Happold (1987) reported its occurrence in Nigeria as rare compared with *G. murinus* (the '*G. murinus*' of Happold (1987) is now known to represent *G. lorraineus*, *G. kelleni* and *G. crassicaudatus*). Based on numbers of specimens in museum collections from countries throughout its distribution, the abundance of this dormouse probably ranges from uncommon to common.

Adaptations Arboreal and probably nocturnal. According to Jeffrey (1973), these dormice climb well, but move slowly on the ground. Nests are often made in hollow trees, and one ♀ made a nest of dry banana fibres inside an old banana plant stem (specimen label). Eight ♀♀ with young trapped in banana groves made their nests of dry banana leaves. Happold (1987) states that these dormice curl up in their nests with the tail folded over the head during the day. Aside from one individual said by the collector, G. L. Bates, to have been 'shot with bow, coming out of hollow tree' (specimen label), all other specimens for which such information is available were taken while sleeping during the day.

Foraging and Food Probably omnivorous. In the wild, foods include cocoa pods, oil palm nuts, paw-paw, bananas and insects (Everard 1968, Happold 1987). Because these dormice are known to nest in hollow trees, and have been taken only among vines or in trees, they presumably do not forage on the ground.

Social and Reproductive Behaviour Apparently solitary, except for lactating ♀♀. Rosevear (1969) reported that this dormouse was less shy and not as easily scared as the smaller dormice occurring in West Africa.

Reproduction and Population Structure Litter-size: probably 2–3. In Liberia, Coe (1975) collected a parous adult in Apr.

In Ghana, G. S. Cansdale trapped several ♀♀ in Sep and Mar with three lactating young whose eyes were not yet opened (specimen labels). In W Ghana, Jeffrey (1973) found eight ♀♀, each nesting with two or three young in Sep, Oct and Nov. In Cameroon, an adult ♀ containing two embryos was found in Feb, and lactating ♀ was caught at the same locality in Apr (Robbins & Schlitter 1981). These very limited data suggest that most young are born during the wetter months of the year, but this needs confirmation.

Predators, Parasites and Diseases Heim de Balsac (1967a) and Jeffrey (1973) state that local people actively hunt *Nagtglas's* Dormice for their prized meat. This dormouse is the type and principal host for the hoplopleurid louse *Schizophthirus aethogliris* (Durden & Musser 1994, Pajot 2000).

Conservation IUCN Category: Least Concern.

Graphiurus ocularis SPECTACLED AFRICAN DORMOUSE (NAMTAP)

Fr. Graphiure du Cap; Ger. Brillen-Bilch

Graphiurus ocularis (Smith, 1829). Zool. J., 4: 439. Near Plettenberg Bay, Cape Province, South Africa.

Taxonomy Originally described in the genus *Sciurus*. In some regions of South Africa, the common name Namtap is used (see Channing 1987 for discussion of other common names applied to this species). Synonyms: *capensis*, *elegans*, *typicus* (see Allen 1939). Subspecies: none. Chromosome number: 2n = 46 (D. N. MacFadyen pers. comm.).

Description Large dormouse. Dorsal pelage medium silvery-grey. Dorsal pelage woolly, thick and moderately long (rump hairs 11–12 mm, guard hairs up to 16 mm). Ventral pelage dark grey washed with white. Dorsal and ventral pelage colours moderately delineated. Head silvery-grey, paler towards muzzle. Eyes large; eye-mask very conspicuous and broad, extending further posteriorly (to beneath the ear) than in other species of *Graphiurus*. Ears brown, moderately large, rounded. Cheeks white, forming part of a white sharply demarcated lateral stripe that extends from cheeks to shoulders. Conspicuous white supra-auricular patches. The combination of broader, more extensive face-mask, white cheeks, pale muzzle and larger, more conspicuous supra-auricular patches results in a striking black-and-white colour pattern on head and shoulders that allows for easy identification of this dormouse based on external characters alone. Hindfeet white and short (24.2 mm) relative to body size. Tail moderately long (ca. 85% of HB), tail hairs shorter at base (10–15 mm) and longer at tip (up to 35 mm). Dorsal tail colour generally matches that of dorsal pelage, but ventral tail colour solid brown-black medially, fringed with white laterally; tip white. Skull long (35.8 mm), moderately flattened (height of braincase 9.3 mm) and moderately broad (19.5 mm). Upper toothrow (3.3 mm) very short, upper premolar circular and very narrow (0.6 mm) both absolutely and relative to skull length; the reduced premolar allows for easy identification of skulls of this species. Anterior palatal foramina of moderate length (3.5 mm) and width (2.2 mm), but short and narrow relative to skull length.

Auditory bullae (9.8 mm) of medium length and only moderately inflated relative to skull length (measurements listed are mean values from Northern and Western Cape Provinces, South Africa; M. E. Holden unpubl.). Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus rupicola. Smaller body length (mean 110 mm). The combination of paler grey dorsal pelage colour, darker muzzle, smaller and less conspicuous white supra-auricular patches and shorter eye-mask (terminating posterior to eye) results in a less striking facial colour pattern. Tail (104.2 mm), ear (17.3 mm) and hindfoot (21.5 mm) absolutely shorter, but relatively longer. Ventral tail colour similar to dorsal tail colour; not darker as in *G. ocularis*. Skull shorter (31.3 mm), interorbital constriction (5.0 mm) absolutely narrower, but relatively broader. Upper toothrow (3.4 mm) similar in absolute length, but longer relative to skull length. Upper premolar broader (0.9 mm) and oval-shaped. Anterior palatal foramina absolutely similar in length (3.4 mm) and breadth (2.3 mm), but relatively longer and broader. Auditory bullae (9.4 mm) absolutely shorter, but relatively longer and more inflated (mean values from Erongo, Karibib, and Mt Brukkaros, Namibia; M. E. Holden unpubl.). Parapatric in Little Namaqualand, Western Cape Province, South Africa. Also occurs in Namibia and Angola.

Distribution Endemic to Africa. South-West Arid (Karoo) and South-West Cape BZs. Recorded in Eastern Cape, Northern and Western Cape Provinces, South Africa. Altitudinal range from near sea level to 1585 m. Other historical distributional records outside the range given here are questionable (Holden 2005).

Graphiurus ocularis

Habitat Spectacled Dormice prefer rock piles, outcrops, crevices and stone kraals (Roberts 1951, Channing 1984, Fox *et al.* 1985, Skinner & Smithers 1990). They have also been captured in huts (Channing 1984) and within the hollow door of a farmhouse (De Graaff & Rautenbach 1983), and there is one report of an individual in a tree (Rautenbach 1982).

Abundance Uncommon. Population densities ranged from 1.8/ha to 3.1/ha on a 7.75 ha study site; densities vary according to the suitability of the habitats (Channing 1984). Smithers (1986a) and De Graaff & Rautenbach (1983) consider it rare.

Adaptations Predominantly rupicolous, also terrestrial. Nocturnal. The flattened cranium allows animals to move through narrow rock crevices. These dormice prefer to travel along rocks above ground level, even if the distance would be considerably shortened by taking a ground-level path (Channing 1997). Fox *et al.* (1985) suggest that these dormice are an early successional species after fire. They remain active throughout the year, but if there is a drop in temperature, and/or a scarcity of food, they can enter torpor for up to a month (Channing 1997, Perrin & Ridgard 1999). In captivity, they were unable to tolerate ambient temperatures greater than 35 °C (Perrin & Ridgard 1999).

Foraging and Food Predominantly insectivorous, occasionally carnivorous. Diet primarily insects and arthropods, although birds and lizards are also taken; probably no seasonal variation in diet (Channing 1984). In captivity, Spectacled Dormice consume

unnatural foods such as crackers, fruit, meat and honey, as well as dog food and rat pellets (Channing 1984, Perrin & Ridgard 1999).

Social and Reproductive Behaviour Spectacled Dormice emit vocalizations and exhibit intimidation displays during disturbance and aggression (Channing 1987, Van Hensbergen & Channing 1989). Fluorescent powder tracking suggests that individuals lay scent trails, and that ♂♂ and ♀♀ follow common routes (Channing 1984, Van Hensbergen & Channing 1989). Home-range (as assessed by harmonic range analysis) is 1.1–2.3/ha for ♀♀ and 2.1–3.8/ha for ♂♂ (Van Hensbergen & Channing 1989). There is some evidence that these dormice may be territorial because pairs remain together in the same area for up to 11 months.

Reproduction and Population Structure Reproductively active in spring and summer. Litter-size: 4–6. Litter interval: 6–8 weeks. Young stay in the nest for 5–6 weeks (Channing 1997). Social structure is primarily male–female pairs with their young of the year. Each pair (with young) occupies the most favourable habitats. Other individuals, including young after leaving their parents, occupy less favourable habitats. Average life-span is thought to be at least four years (Channing 1984).

Predators, Parasites and Diseases Ectoparasites include species of three families of fleas (Hystriopsyllidae, Listropsyllidae and Chimaeropsyllidae) and the tick *Rhipicephalus simus* (De Graaff 1981).

Conservation IUCN Category: Least Concern.

The categorization of this species should be changed to Near Threatened, or at least Data Deficient, due to its discontinuous distribution and poor representation in museum collections. Smithers (1986) categorized the species as rare.

Measurements

Graphiurus ocularis

Graphiurus platyops FLAT-HEADED AFRICAN DORMOUSE

Fr. Graphuïre à tête plate; Ger. Flachkopf-Bilch

Graphiurus platyops Thomas, 1897. Ann. Mag. Nat. Hist., ser. 6, 19: 388. Enkeldorn, Mashonaland, S Zimbabwe.

Taxonomy Ellerman *et al.* (1953) synonymized *G. rupicola* from NW South Africa and Namibia, and *G. angolensis* (including *parvulus*) from Angola and NW Zambia within this species. Their arrangement was generally followed by Genest-Villard (1978a), though she placed the Angolan populations (*G. angolensis* and *parvulus*) as junior synonyms of *G. murinus*. Allen (1939) recognized *G. platyops*, *G. rupicola* and *G. angolensis*, as well as *parvulus* (listed here as a junior synonym of *G. angolensis*) as separate species. Roberts (1951) also treated *G. rupicola* and *G. platyops* as distinct species, a position followed by Holden (1993, 2005) based on comparisons of museum specimens. Following Ansell (1978), Holden (1993) provisionally listed *angolensis* and *parvulus* as synonyms of *G. platyops*, but analyses of museum specimens (M. E. Holden unpubl.) support recognition of the Angola and NW Zambia population as a separate valid species, *G. angolensis* (including *parvulus*). Synonyms: *eastwoodae*, *jordani* (see Holden [2005] regarding allocation of *albicaudatus*, a name that apparently was never published). Subspecies: none. Chromosome number: $2n = 46$ (D. N. MacFadyen pers. comm.).

Description Medium-sized dormouse. Dorsal pelage grey, brownish-grey or greyish-brown. Pelage sleek and moderately long (rump hairs 10 mm, guard hairs up to 13 mm). Ventral pelage white or cream suffused with grey. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage, paler towards muzzle. Eyes large; eye-mask conspicuous. Ears brown, moderately large, rounded. Cheeks white, forming part of a pale lateral stripe that extends from cheeks to shoulders. Faint white postauricular patches sometimes present. Hindfeet usually white, sometimes with dark metatarsal streak. Tail moderately short (ca. 71% HB), similar in colour to dorsal pelage, with many scattered white hairs; hairs shorter at base (5–7 mm) and longer at tip (up to 30 mm); tip white. Skull gracile, broad (17.1 mm) and flat (height of braincase 7.8 mm). In lateral profile, dorsal outline of skull from rostrum to occiput is practically horizontal. Interorbital constriction moderately broad (4.8 mm), anterior palatal foramina moderately long (3.2 mm), but somewhat short relative to skull length. Upper tooththrow relatively short (3.1 mm) and narrow as exhibited by narrow breadth of upper premolar (0.8 mm). Auditory bullae of medium length (8.4 mm) and only moderately inflated relative to skull length (measurements listed are mean values from Zimbabwe and NE South Africa; M. E. Holden unpubl.). Nipples: $1 + 1 + 2 = 8$.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus microtis. Smaller head and body length (mean 98.8 mm). Tail (75.2 mm) absolutely shorter, but relatively longer. Hindfeet (16.9 mm) shorter, and ears (15.5 mm) longer, both absolutely and relatively. Dorsal pelage greyish-brown to dark greyish-brown in populations sympatric with *G. platyops*. Skull shorter (27.4 mm), vaulted and relatively narrower (15.0 mm). Although

*Graphiurus platyops*

the height of braincase (7.5 mm) is absolutely shorter in *G. microtis*, in lateral view the braincase is markedly more vaulted and its dorsal outline convex. It is also relatively higher relative to skull length. Upper tooththrow (3.0 mm), anterior palatal foramina (3.4 mm) and auditory bullae (8.1 mm) similar to slightly shorter in length, so relatively longer. Anterior palatal foramina 3.4 mm long, 2.1 mm wide. Interorbital constriction (3.9 mm) absolutely and relatively narrower (measurements listed are mean values from Zimbabwe; M. E. Holden unpubl.). Generally sympatric throughout range of *G. platyops*, but seems to be segregated by habitat, and is probably not syntopic. *Graphiurus microtis* occurs in savannas throughout most of sub-Saharan Africa.

Distribution Endemic to Africa. Southern part of Zambezi Woodland BZ and northern part of Highveld BZ. Recorded from NE and S Zambia, Zimbabwe, S Malawi, E Botswana, S Mozambique and NE South Africa (Holden 2005). Previously thought to occur in C Botswana (De Graaff 1981); however, the museum specimen on which the record was based is *G. microtis* (Holden 2005).

Habitat Flat-headed African Dormice are most often trapped in crevices in rock kopjes, krantzies and under exfoliating granite (Roberts 1951, Smithers 1971, 1983, Wilson 1975). They have sometimes been found in association with dassies (*Heterohyrax* and *Procavia*) (Roberts 1951, Smithers & Lobão Tello 1976). Three individuals were trapped in caves in South Africa (specimen labels). On the Save R., Mozambique, individuals were collected in dry *Androstachys* sp. scrub thickets in a dry river bed (Smithers & Lobão

Tello 1976). In NE South Africa, one ♀ with three young was caught in a hollow tree branch (Roberts 1951). Rautenbach (1982) observed that this species generally occurs at altitudes higher than 609 m, and is not associated with mopane woodland.

Abundance Little information. Uncommon in E Zambia (Ansell 1978). There are only ca. 50 museum specimens of *G. platyops*, and usually only one or two individuals have been found at each locality, suggesting that even in suitable habitat, densities are not high.

Adaptations Predominantly rupicolous. The markedly flattened cranium allows movement of these animals through narrow rock crevices, where they are most commonly found. Most authors characterize this dormouse as being nocturnal (e.g. Smithers 1971), but five individuals trapped by Wilson (1975) in W Zimbabwe were taken between 06:00 and 09:00h, suggesting that at least some individuals are crepuscular or diurnal.

Foraging and Food Omnivorous. Stomach contents of individuals from Zimbabwe and Botswana contained remains of well-masticated small seeds, traces of green vegetable matter and the chitinous remains of insects, including moths (Smithers 1983). One animal was trapped using a portion of a rat carcass for bait (specimen label).

Social and Reproductive Behaviour Apparently solitary (Smithers 1983). Unbaited tunnel traps that have been entered by one individual seem to attract others, suggesting that, like Spectacled Dormice, these dormice use scent trails (Channing 1997). They are aggressive, flourishing and whipping their tails as a visual signal (Channing 1997). Vocalizations include a soft warning call, consisting of a number of short, low-pitched notes. An aggression call follows if the intruder does not leave. The aggression call consists of a series of brief spits, each consisting of a 0.1-second burst of high amplitude

white noise. The encounter escalates into a fight if the intruder remains (Channing 1997).

Reproduction and Population Structure Little information. In Zimbabwe, a pregnant ♀ carrying two full-term embryos was obtained in Feb (specimen label).

Predators, Parasites and Diseases Flat-headed African Dormice are hosts of the chimaeropsyllid flea *Chiaestopsylla nama*, which also occurs on other rupicolous rodents including *Aethomys namaquensis* and *Petromyscus collinus* (Haeselbarth *et al.* 1966, De Graaff 1981).

Conservation IUCN Category: Least Concern.

Little information is known regarding distribution and abundance; a more appropriate categorization would be Data Deficient.

Graphiurus rupicola RUPICOLOUS AFRICAN DORMOUSE

Fr. Graphiure des rochers; Ger. Felsen-Bilch

Graphiurus rupicola (Thomas and Hinton, 1925). Proc. Zool. Soc. Lond. 1925: 232. Karibib, Namibia. 3842 ft (1170 m).

Taxonomy Originally described in the genus *Gliriscus*. Ellerman *et al.* (1953) and Genest-Villard (1978a) considered *rupicola* to be a subspecies of *G. platyops*. Roberts (1951) recognized the substantial morphological differences between *rupicola* and *platyops*, and listed *G. rupicola* as a separate species, an arrangement followed here. Synonyms: *australis*, *kaokoensis*, *montosus*. Subspecies: none. Chromosome number: not known.

Description Medium-sized dormouse. Dorsal pelage silvery-grey, drab grey or slate-grey. Dorsal pelage woolly, thick and moderately long (rump hairs 10–11 mm, guard hairs up to 17 mm). Ventral pelage white or cream lightly suffused with dark grey. Dorsal and ventral pelage colours clearly delineated. Head colour matches that of dorsal pelage, slightly paler towards muzzle. Eyes large; eye-mask conspicuous. Ears brown, large, oval-shaped. Cheeks cream or white, forming part of a pale lateral area that extends from cheeks to shoulders. Cream supra-auricular patches, and faint

postauricular patches present. Hindfeet white, or white with dark metatarsal streak. Tail long (ca. 95% HB), similar in colour to dorsal pelage, with many scattered white hairs; hairs shorter at base (9–12 mm) and longer at tip (up to 43 mm); white at tip. Skull long and moderately flattened (height of braincase 8.0 mm). Palate long (10.4 mm), upper premolar breadth (0.88 mm) somewhat narrow relative to skull length, interorbital constriction (5.0 mm) broad, anterior palatal foramina moderately long (3.4 [3.1–3.6] mm) and wide (mean 2.3 mm), auditory bullae long (9.4 mm) and inflated relative to skull length (measurements are mean values from Erongo, Karibib and Mt Brukkaros, Namibia; M. E. Holden unpubl.). Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only) *Graphiurus angolensis*. Slightly smaller body length (mean 98.8 mm).

Tail (79.2 mm) and hindfeet (18.4 mm) are absolutely and relatively shorter. Dorsal pelage is drab or dark brown. Skull averages slightly shorter (28.2 mm). Although height of braincase (7.7 mm) is absolutely shorter in *G. angolensis*, in lateral view the braincase appears more vaulted and its dorsal outline is more convex. Interorbital constriction (4.2 mm) absolutely narrower and auditory bullae (8.9 mm) absolutely shorter but relatively longer. Upper premolar breadth (0.90 mm) absolutely similar but broader relative to skull length. Anterior palatal foramina absolutely similar in length (3.4 mm) but relatively longer (measurements listed are mean values from Kabompo and Zambezi [formerly Balovale], Zambia; M. E. Holden unpubl.). Parapatric in C Angolan highlands, occurs in Angola and NW Zambia.

Graphiurus microtis. Slightly smaller body length (mean 98.8 mm). Tail (75.2 mm) and hindfeet (16.9 mm) are absolutely and relatively shorter. Dorsal pelage sometimes similar in colour, especially in Namibia, Botswana and NE South Africa populations. Skull markedly shorter (27.4 mm). Palate (8.8 mm) shorter, interorbital constriction (3.9 mm) narrower, and auditory bullae (8.1 mm) shorter both absolutely and relatively. Upper tooththrow (3.0 mm) absolutely shorter, but relatively similar. Upper premolar breadth (0.85 mm) absolutely narrower, but broader relative to skull length. Anterior palatal foramina 3.4 mm long, 2.1 mm wide, similar in length, so relatively longer (measurements listed are mean values from Zimbabwe; M. E. Holden unpubl.). Sympatric near Okahandja, Namibia; occurs in savannas throughout sub-Saharan Africa.

Graphiurus ocularis. Larger body length (mean 134.3 mm). Tail (114.5 mm), ear (19.4 mm) and hindfeet (24.2 mm) are absolutely longer, but relatively shorter. Dorsal pelage darker grey with striking facial colour pattern. Dorsal tail darker than ventral tail colour. Skull (35.8 mm) longer. Palate (12.0 mm) absolutely longer, but relatively similar. Interorbital constriction (5.4 mm) absolutely broader, but relatively narrower. Auditory bullae

(9.8 mm) slightly longer and upper tooththrow (3.3 mm) similar, but both shorter relative to skull length. Anterior palatal foramina absolutely similar in length (3.5 mm) and breadth (2.2 mm), but relatively shorter. Upper premolar circular and greatly reduced in size (breadth 0.6 mm) (measurements listed are mean values from Northern and Western Cape Provinces, South Africa; M. E. Holden unpubl.). Parapatric in Little Namaqualand, Western Cape Province, South Africa; also occurs in Eastern and Northern Cape Provinces.

Distribution Endemic to Africa. South-West Arid BZ (with possible northern extension to Zambezian Woodland BZ in Angola). Occurs on central mountains and plateaux from Mt Soque, Angola, south to Port Nolloth and Eenriet in Little Namaqualand, South Africa (Holden 2005). The northern distributional limit for *G. rupicola* was previously thought to be Kamanjab, Namibia, but specimens from Mt Soque, Angola, are considered to represent this species (Holden 2005). A specimen from Dilolo, DR Congo, resembles *G. rupicola* in pelage characters, but resembles *G. monardi* in skull characters; at present the specimen cannot be allocated to either species (Holden 2005).

Habitat Rock crevices in rocky outcrops and kopjes, from altitudes of 400 m to at least 1586 m. Most specimens were caught in bushy Karoo–Namib shrubland or Karoo transition vegetation zones; two specimens from Mt Soque, Angola, were captured in ‘evergreen wood at mountain top’ (specimen label).

Abundance Little information. Roberts (1951) considered the species to be rare, an observation supported by the few specimens (ca. 20) in museums.

Remarks The moderately flattened skull enables animals to squeeze through narrow rock crevices. The very few habitat notes (Shortridge 1934, Roberts 1951; specimen labels) suggest that *G. rupicola* nests only in rock crevices. A ♀ obtained on Mt Brukkaros, Namibia, in Sep was pregnant (specimen label).

Conservation IUCN Category: Least Concern.

So little is known about the species that a classification of Data Deficient may be more appropriate.

Graphiurus rupicola

Graphiurus surdus SHORT-EARED AFRICAN DORMOUSE

Fr. Graphiure sourd; Ger. Kurzohr-Bilch

Graphiurus surdus Dollman, 1912. Ann. Mag. Nat. Hist., ser. 8, 9: 314. Benito River, Rio Muni Province, Equatorial Guinea.

Taxonomy Although described and initially recognized as a species, *G. surdus* was later synonymized within a broadly defined *G. murinus* (Misonne 1974, Genest-Villard 1978a). Robbins & Schlitter (1981) and Holden (1996) provided morphological evidence for recognizing *G. surdus* as a valid species. Synonym: *schwabi*. Subspecies: none. Chromosome number: not known.

Description Small to medium-sized dormouse. Dorsal pelage greyish-brown. Dorsal pelage silky and moderately long (rump hairs 5–7 mm, guard hairs up to 11 mm). Ventral pelage dark grey washed with whitish-buff. Dorsal and ventral pelage colours not clearly delineated. Head colour matches that of dorsal pelage. Eyes large; eye-mask inconspicuous. Ears brown, short and rounded. Cheeks grey washed with white. Postauricular patches not present. Hindfeet cream or white with dark metatarsal streak. Tail moderately long (ca. 73% of HB), similar in colour to dorsal pelage, with many scattered white hairs resulting in a frosted appearance; hairs shorter at base (3–8 mm) and longer at tip (up to 20 mm); tip not white. Skull medium length (27.6 mm), moderately vaulted (height of braincase 8.1 mm), with narrow greatest width of skull (14.6 mm), and comparatively straight conformation of the zygomatic arch in lateral view (figured in Robbins & Schlitter 1981 and Holden 1996). Interorbital constriction (4.5 mm) narrow. Anterior chamber of auditory bullae markedly less inflated than posterior chambers in most individuals. Anterior palatal foramina relatively short (2.8 mm) and narrow (1.8 mm). Upper premolar narrow (0.8 mm), palate long (9.3 mm) and auditory bullae short (7.3 mm) and uninflated relative to skull length (measurements listed are mean values from Cameroon, Equatorial Guinea and Gabon; Holden 1996). Nipples: 1 + 1 + 2 = 8.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Graphiurus christyi. Similar head and body length (mean 97.6 mm). Ears longer (14.2 mm). Dorsal pelage colour sometimes similar, but most individuals have a rufous hue. Eye-mask usually more distinct. Tail absolutely and relatively longer (ca. 83% of HB). Skull averages slightly shorter (97.8 mm). Palate shorter (8.5 mm) both absolutely and relative to skull length. Anterior palatal foramina absolutely similar in length (3.0 mm), but absolutely and relatively wider in breadth posteriorly (2.2 mm). Auditory bullae similar in length (7.4 mm) and relative inflation. (Measurements listed are mean values from DR Congo; M. E. Holden unpubl.). No sympatry recorded, though both species have been collected in SW Cameroon and N DR Congo (Holden 1996).

Graphiurus lorrainaeus. Smaller head and body length (mean 83 mm). Hindfeet (16.6 mm) shorter. Ears similar in size, but relatively larger. Dorsal pelage usually rufous, though sometimes brown. Anterior palatal foramina 2.6 mm long, 1.7 mm wide. Skull

(24.5 mm) much shorter, and palate absolutely and relatively shorter (7.8 mm). Similar average length of auditory bullae (7.1 mm) and breadth of upper premolar (0.8 mm), but bullae are longer and upper premolar is wider relative to skull length. Anterior palatal foramina absolutely similar in length (2.6 mm), but relatively somewhat longer (measurements listed are mean values from DR Congo; M. E. Holden unpubl.). Sympatric in SW Cameroon, Equatorial Guinea and DR Congo (Holden 1996).

Graphiurus crassicaudatus. Smaller head and body length (92.6 mm). Hindfeet (17.7 mm) and tail (59.4 mm) shorter. Dorsal pelage usually rufous-brown. Skull shorter (26.6 mm). Greatest width of skull (16.1 mm) and interorbital constriction (4.9 mm) markedly broader relative to skull length, supraorbital ridges present. Palate (9.4 mm) similar in length but relatively longer. Upper tooththrow (3.8 mm) absolutely and relatively longer (measurements listed are mean values from S Cameroon; M. E. Holden unpubl.). Sympatric in SW Cameroon; occurs in West and west-central Africa.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Gabon Subregion], and marginally East Central and South Central Regions). Recorded from two disjunct areas in central Africa: (1) S Cameroon south to Equatorial Guinea and Gabon; (2) NE Congo (Masako) and SC Congo (Inkongo). Of the 22 known specimens, 15 are from S Cameroon. Limits of geographic range unknown.

*Graphiurus surdus*

Habitat Probably occurs in primary rainforest; may also be found in secondary forest (specimen labels). These dormice have been trapped on the forest floor (W. Verheyen pers. comm.), and in forests with vines (Robbins & Schlitter 1981).

Abundance Little information. Most specimens are from localities that have been fairly well sampled. This suggests either low population densities, or that the species is trap-shy, or that traps have not been set in appropriate habitats.

Remarks Arboreal. One individual collected by G. L. Bates from Bitye, Cameroon was ‘smoked out of a hollow tree’ (specimen label). This suggests that, like *G. crassicaudatus*, *G. nagtglasii* and *G. lorraineus*, some individuals nest in hollow trees.

Conservation IUCN Category: Data Deficient.

Family DIPODIDAE

JERBOAS

Dipodidae Fischer de Waldheim, 1817. Mem. Soc. Imp. Nat., Moscow 5: 372.

| | | |
|------------------------------|------------------|--------|
| <i>Allactaga</i> (1 species) | Four-toed Jerboa | p. 136 |
| <i>Jaculus</i> (2 species) | Jerboas | p. 137 |

The Dipodidae contains 51 species arranged in six subfamilies and 16 genera (Holden & Musser 2005). The family is distributed throughout the Palaearctic region, the Middle East and North Africa in forests, grasslands and steppe, and in hot and cold deserts. Only two genera and three species of this widespread family occur in Africa.

The taxonomy of the family is controversial and uncertain. The family appears to be monophyletic (Holden & Musser 2005 and references therein) and to have diversified greatly in recent times. The family is divided into six subfamilies: Sicistinae (birch mice) with the single genus *Sicista*, Zapodinae (jumping mice) with *Zapus*, *Eozapus* and *Napeozapus*, Cardiocraniinae with *Cardiocranius*, *Salpingotus* and *Salpingotulus*, Euchoreutinae with *Euchoreutes*, Allactaginae with *Allactaga*, *Allactodipus* and *Pygeretmus*, and Dipodinae with *Dipus*, *Eremodipus*, *Jaculus*, *Paradipus* and *Stylodipus*. Only the Allactaginae and Dipodinae occur in Africa. The family as a whole is characterized by enlarged masseter muscles, which penetrate the infraorbital foramen (a character normally associated with hystricomorph rodents), an enlargement of the jugal to form a plate anterior to the orbit, which protects the eye, and the lack of a bony inflection on the angle of the mandible (which is characteristic of most murid rodents). Two of the subfamilies, the Sicistinae and Zapodinae, differ from the other four in many respects and some authorities place these subfamilies in a separate family, the Zapodidae; however, there is considerable overlap in characters between all the subfamilies and no clear dividing lines separating each subfamily. Because, on balance, Sicistinae and Zapodinae are similar to each other, with marked differences to the remaining subfamilies, the Dipodidae are here regarded as separate from the Zapodidae (Corbet & Hill 1986); this arrangement reduces the family Dipodidae to four subfamilies, 12 genera and 33 species. See Holden & Musser (2005) for further details.

The best-known characters of Dipodidae (as understood here) are large auditory bullae, non-cuspidate low-crowned cheekteeth, long hindlimbs (ca. 50–56% of HB in African species), reduction in the number of digits, elongation of the metatarsal bones and partial or total fusion of these bones to a form a single ‘cannon bone’, which supports the weight of the body, a flattened nasal region reminiscent of that of a pig, large (or very large) ears and large dark eyes. The neck is short and the vertebrae are small and fused in most species. The metatarsal bones and the phalanges of the hindfeet are very specialized and varied in structure. In *Cardiocranius* there are five hind digits (Digit 1 being the shortest) and the metatarsal bones are not fused; in *Salpingotus* Digits 1 and 5 are lost and the metatarsals are not fused; in *Allactaga* the metatarsals of Digits 2, 3 and 4 are fused (now called the ‘cannon bone’) and Digits 1 and 5 are very short and lie close and parallel to the cannon bone (in *A. tetradactyla*, Digit 1 on the inner side of the hindfoot is absent); and in *Jaculus* and *Dipus* the cannon bone is extremely elongated and Digits 1 and 5 are absent. In all species with a cannon bone, the three hind digits are well developed. In contrast to the hindlimbs,

the forelimbs are very short, have five digits and are rarely used for locomotion. The very long tail (ca. 140–170% of HB in African species) has a tuft of hairs at the tip and is used as a counterbalance during rapid running or hopping locomotion. When the long-legged species (*Jaculus*, *Dipus*, *Allactaga*) are resting on the hindlimbs, the end of the tail near the tip provides a tripod-like support. There are several modes of locomotion; the most typical is a fast bipedal jump using only the two hindlimbs (‘richochetal locomotion’). The skull is broad, and has an enlarged jugal plate, well-developed auditory bullae and laminate molars. The mandibles are weak without a bony inflection at the angle of the mandible, and perforations (fossae) on the angular process. Dental formula is: $I \frac{1}{1}, C \frac{0}{0}, P \frac{0}{0}, M \frac{3}{3} = 16$ (P is $\frac{0}{1}$ in some non-African species). Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

All species of the Dipodidae live in open, usually arid, habitats where vegetation is sparse. The climate where dipodids live is extremely varied: species that live the cold deserts of Asia hibernate for 6–7 months during the coldest season of the year, and some species (*Cardiocranius*, *Salpingotus*, *Pygeretmus*) store fat in their tails. Species living in hot deserts are lethargic, and exhibit less activity, during the coolest part of the year. During the day they rest in burrows, which may be up to 3 m underground and extend for many metres; when inside the burrow, some species block the entrance with a plug of sand. Individuals emerge at night to forage on the ground. Species with long legs hop and run over the substrate with great speed and agility. The diet is principally seeds, bulbs and grass stalks; some species may feed occasionally on insects. Species that live in arid habitats (e.g. *Jaculus* spp.) possess kidneys that have special anatomical features to minimize water loss. Little information is available on the social behaviour in dipodids; they are usually found singly or in small groups; during cold weather, several individuals often huddle together in a nest in the burrow. Reproduction is seasonal, litter-size is mostly 2–6, and ♀♀ of some species may have more than one litter each breeding season.

Fossil remains of dipodids are uncommon. Fossil jumping mice and jerboas are known from the Pliocene of Europe and from the Miocene and Pliocene of Asia. There are very few fossil remains of jerboas from Africa (Holden & Musser 2005).

In Africa, there are two subfamilies and two genera:

Allactaginae: five digits on hindfoot (four in *A. tetradactyla*), three metatarsals (Digits 2, 3 and 4) fused to form cannon bone, undersurface of hind digits with small hairs, three molars and one small premolar in each upper jaw; *Allactaga* (1 sp.).

Dipodinae: three digits on hindfoot; three metatarsals (Digits 2, 3 and 4) fused to form cannon bone, undersurface of hind digits with abundant strong bristles, three cheekteeth without premolar in each upper jaw; *Jaculus* (2 spp.).

D. C. D. Happold

GENUS *Allactaga*

Jerboas

Allactaga F. Cuvier, 1836. Proc. Zool. Soc. Lond., 1836: 141 [1837]. Type species: *Mus jaculus* Pallas, 1778 (= *Dipus sibericus major* Kerr, 1792).

Allactaga tetradactyla.

Widespread genus with 11 species in 'cold deserts' from Iran and Afghanistan to Manchuria, and in 'hot deserts' of the Middle East and NE Africa (Holden 1993). Holden & Musser (2005) place *Allactaga* as the only genus in the subfamily Allactaginae.

The principal characters of the genus are: fusion of the metatarsal bones of Digits 2, 3 and 4 to form the 'cannon bone' (as in *Jaculus*). In most species, Digit 1 is short, although it is absent in *A. tetradactyla* (the only species of this genus in Africa). Digit 5 (outer digit) is short, ending half way along the length of the cannon bone. In general shape, *Allactaga* is reminiscent of *Jaculus*, except that the ears are much longer and often held upright from the head. Hindlimbs used for synchronized bipedal hopping, and for asynchronized bipedal trotting. Very long tail acts as counterbalance when hopping. Large eyes and ears. Pads of digits large and naked. The skull is characterized by a rudimentary premolar in each upper jaw (cf. *Jaculus*), perforations in the small angular process of the lower jaw, large auditory bullae but less developed than in *Jaculus*, well developed maxillary process, large orbit and wide zygoma (Figure 20). Baculum absent.

The single African species, *Allactaga tetradactyla*, is present only in Egypt and Libya.

Allactaga tetradactyla FOUR-TOED JERBOA

Fr. Gerboise tétradactyle; Ger. Vierzehen-Jerboa

Figure 20. Skull and mandible of *Allactaga tetradactyla* (BMNH 14.3.6.1).

Allactaga tetradactyla (Lichtenstein, 1823). Verz. Doublet. Zool. Mus. Univ. Berlin, p. 2. 'Libyan Desert between Siwa and Alexandria' (= Egypt).

Taxonomy Originally described in the genus *Dipus*. Synonyms: *brucii*. Subspecies: none. Chromosome number: not known.

Description Small jerboa with large rounded head, extremely long hindlimbs, four toes on each hindfoot, and very long tufted tail. Dorsal pelage pale orange streaked with black, tending to grey on the flanks; hairs grey at base, orange on terminal half, sometimes with black tip. Ventral hairs pure white, without white colouration extending onto rump at base of tail. Head similar in colour to dorsal pelage. Eyes large. Ears long and darkly pigmented. Hindlimbs,

especially metatarsals, very long (ca. 51% of HB). Digits 2, 3 and 4 fused to form cannon bone; Digit 1 absent; Digit 5 short, ending with short claw visible about half way along outer surface of cannon bone (*contra* Kingdon 1997:191; inner digit [Digit 1] shown on right cannon bone is in error). Undersurface of cannon bone and base of toes with blackish hairs. Tail very long (ca. 150% of HB), with terminal tuft of black hairs, each hair black at base with white tip. Skull as in genus profile. Nipples: not known.

Geographic Variation None recorded.

*Allactaga tetradactyla*

Similar Species

Jaculus jaculus: Similar in general size, shorter ears (21 mm); three hind digits, Digits 1 and 5 absent.

Jaculus orientalis. Much larger (HB: 137–160 mm; HF: 71–78 mm); three hind digits, Digits 1 and 5 absent.

Distribution Endemic to Africa. Eastern part of Sahara Arid BZ. Regs and hamadas along the Mediterranean coast of Libya and Egypt west of the Nile Delta. Does not extend southwards into the Sahara Desert.

Habitat Salt marshes and valleys in coastal regions; further inland, recorded from clay deserts, especially near barley fields, and *Anabasis* shrublands (Osborn & Helmy 1980).

Abundance Rare and localized. Much less common than *J. orientalis*, which lives in similar habitats.

Remarks Terrestrial and nocturnal. Many of the adaptations of these jerboas are likely to be similar to those of the two species of *Jaculus*, but their rarity precludes detailed information. However, unlike *Jaculus* spp., Four-toed Jerboas appear to have a very limited ecological tolerance. Burrows are simple, 60–150 cm deep. Burrows are occupied only for brief periods; at other times unoccupied burrows of Greater Egyptian Jerboas are utilized (Hoogstraal 1963). Occasionally infested by the flea *Xenopsylla nubica*, and by four other species of fleas. Another flea species, *Hopkinsiopsylla occulta*, is species-specific to *A. tetradactyla*, and is mostly found in the nests and not on the host itself. Only 25 animals (of 200 examined) were infected by fleas (Hoogstraal & Traub 1965b).

Conservation IUCN Category: Vulnerable. This species is threatened with extinction because of its rarity, small geographical range and reclamation of its habitat for agriculture and development (Hoogstraal 1963).

GENUS *Jaculus*

Jerboas

Jaculus Erxleben, 1777. Syst. Regni Anim. 1: 404. Type species: *Mus jaculus* Linnaeus, 1758.

Widespread genus with three species in arid habitats of North Africa and the Middle East, extending eastwards to western Pakistan and northwards to Turkmenistan and Uzbekistan (Holden 1993). The genus is placed in the subfamily Dipodinae, together with the non-Africa genera *Dipus* (1 sp.), *Eremodipus* (1 sp.), *Paradipus* (1 sp.) and *Stylodipus* (3 spp.). Two species of *Jaculus* occur in Africa.

The principal characters of the genus are elongated hindlimbs and fusion of the metatarsals of Digits 2, 3 and 4 to form a 'cannon bone' (as in *Allactaga*); Digits 1 and 5 absent. Hindlimbs used for synchronized bipedal hopping, and for asynchronized bipedal trotting. Very long tail acts as counterbalance when hopping. Eyes very large. Ears large, rounded at tip. Pads of digits small and covered with dense bristles. Lacks small premolar in upper jaw (cf.

Allactaga). Skull broad, auditory bullae greatly inflated and elongated (ca. 40% of GLS), zygoma absent (c.f. *Allactaga*), large orbit, and with perforations in small angular process of lower jaw (Figure 21). Baculum present.

Members of the genus are highly adapted for life in sandy arid habitats where the climate is alternately very hot during the day and cool or cold at night. They are nocturnal, and spend the day in deep burrows. The diet is seeds and dried grass. They are independent of free water, primarily because they have efficient kidneys that produce very concentrated urine.

Fossils of the genus are known from the late Miocene of Kazakhstan, late Pliocene of Morocco and Ethiopia, and Pliocene-Pleistocene of Kenya (details in Holden & Musser 2005).

Figure 21. Skull and mandible of *Jaculus jaculus* (HC 504).

Two species are present in Africa: one widespread and common in North Africa; the other confined to the Mediterranean coastal zone. The species are distinguished by body size and geographical distribution.

***Jaculus jaculus* LESSER EGYPTIAN JERBOA**

Fr. Petite Gerboise d’Egypte; Ger. Kleine Ägyptische Springmaus

Jaculus jaculus (Linnaeus, 1758). Syst. Nat., 10th edn, 1: 63. Giza Pyramids, Egypt.

Taxonomy Originally described in the genus *Mus*. About 19 subspecies (Misonne 1974) have been described throughout the extensive African range of the species. Individual countries may have several subspecies, e.g. Algeria five subspp. (Kowalski & Rzebik-Kowalska 1991), Egypt four subspp. (Osborn & Helmy 1980), Libya eight subspp. (Ranck 1968) and Sudan two subspp. (Setzer 1956). Some of these taxa were used as specific names in the past, but now all are regarded as synonyms (Holden & Musser 2005). *Jaculus deserti*, as recorded by Ranck (1968) in Libya, is a synonym of *J. jaculus* (Osborn & Helmy 1980; Musser & Carlton 1993). Synonyms (of *J. jaculus*): *airensis*, *arenaceus*, *butleri*, *centralis*, *collinsi*, *cufensis*, *favonicus*, *gordoni*, *microtis*, *sefrius*, *tripolitanicus*, *vulturinus*, *whitchurchi*; (of *J. deserti*): *favillus*, *fuscipes*, *rarus*, *schlüteri*, *vastus*. Subspecies: none (but see Geographic Variation). Chromosome number: $2n = 50$; $FN = 90$ (Senegal; Granjon *et al.* 1992); $2n = 48$ (Niger; Dobigny *et al.* 2002b).

Description Small pale-coloured jerboa with large rounded head, extremely long hindlimbs and very long tufted tail. Dorsal pelage long and silky, pale sandy-brown to sandy-rufous; hairs grey at base, sandy or brownish on terminal half, sometimes with black tip. Black-tipped hairs more numerous in individuals from moister habitats resulting in a streaked darker-coloured pelage. Ventral pelage pure white. White colouration extends dorsally onto rump forming white band at base of tail. Head similar in colour to back, broad and rounded, with small muzzle, many vibrissae, large eyes and large rounded ears. Hindlimbs, especially metatarsal bones, very long (ca. 56% of HB); three hind digits well covered on undersurface with whitish bristles. Forelimbs small, held close

Jaculus jaculus

under chin. Tail very long (ca. 170% of HB), basal two-thirds covered with short sandy-coloured hairs; terminal third with long hairs forming a large tuft, black on basal half, white on terminal half. Skull as in genus profile. Females tend to be heavier than ♂♂ (adult mean weights at Khartoum: ♀♀ [non-pregnant] 60 g; ♂♂ 49 g). Nipples 2 + 2 = 8.

Geographic Variation Colour of dorsal pelage (the basis for most subspecies descriptions) appears to be related to the colour of the soil or sand and the degree of aridity. Individuals from C Sahara are very pale sandy- or creamy-white (e.g. *airensis*), those from moister environments are sandy-brown to orange-brown with greater numbers of black-tipped hairs. Mean HB length varies with locality (and 'subspecies'): e.g. 105 mm (*butleri*, Khartoum); 110 mm (*jaculus*, Egypt); 111 mm (*flavillus*, Egypt).

Similar Species

J. orientalis. Larger (HB: 137–160 mm; HF: 71–78 mm); North African coastal regions only.

Allactaga tetradactyla. Similar in general size, ears longer (40 mm), four digits including short Digit 5 on outside of cannon bone; coastal regions Libya and Egypt only; rare.

Distribution Sahara Arid and Sahel Savanna BZs. Recorded from S Morocco, Mauritania and N Senegal in the west to Egypt and Sudan in the east. Not recorded in the coastal regions of Morocco north of the High Atlas and Saharan Atlas mountains of Morocco and Algeria. Isolated populations in coastal Eritrea, coastal Ethiopia and N Somalia. Perhaps occurs in Djibouti. There is some evidence that, since the 1970s, the distribution of jerboas has been moving progressively southwards within the Sahel Savanna BZ and into the Sudan Savanna BZ as a result of desertification of the savannas by humans. Also recorded from Israel, Iraq, Iran, Syria, Pakistan and Saudi Arabia.

Habitat Lesser Egyptian Jerboas live in a variety of open sparsely vegetated arid and semi-arid habitats, including loose sandhills and hillocks, sandy plains and wide sandy wadis. Also occur on flat solid substrates, such as coastal regions and higher altitude plateaux (up to ca. 1500 m), provided the sand or soil is suitable for burrowing. Also recorded near fields of barley, and in *Anabasis* steppe country, along the Mediterranean coast. Not found in rocky habitats or on jebels.

Their ability to live in many arid zone habitats and climates is one reason for their wide distribution.

Abundance In most habitats, Lesser Egyptian Jerboas are never abundant and distribution is patchy; tend to be rare over much of their geographic range especially where soil type is unsuitable, rainfall is very low and where food resources are limiting. Usually never abundant in Egypt (Osborn & Helmy 1980). Comparatively common in selected habitats near Khartoum (Happold 1967a, c, 1975a), and recorded as 'common on the meidan' in Somalia (specimens in BMNH, collected 1912). Where the three species of jerboas occur parapatrically, as in parts of Egypt, this species is rare (Hoogstraal & Traub 1965b).

Adaptations Nocturnal and terrestrial. Lesser Egyptian Jerboas emerge from burrows after dusk. They exhibit several methods of locomotion above ground (Figure 22) including walking on all four limbs when foraging for food, hopping bipedally and slowly when 'pottering', and hopping very quickly when escaping from danger. Occasionally they run with a fast bipedal trot (Happold 1967a). The tail is held out horizontally as a counterbalance when moving on the hindlimbs. They gain friction on the substrate from bristles on undersurface of the hindfeet. When disturbed or pursued, they hop extremely rapidly (up to ca. 30 km/h), often changing direction quickly and erratically. Mobility is necessary to find adequate food, and speed and manoeuvrability are essential to escape from predators in open environment. Lesser Egyptian Jerboas groom by licking their fur and by lying in a little concavity in the sand with the hindlimbs stretched out and rubbing the body backwards and forwards ('sand-bathing').

Lesser Egyptian Jerboas dig burrows in the sand using their teeth and forefeet to excavate the burrow, and push the excavated sand out of the burrow with the blunt flattened nose and muzzle (nostrils can be closed), and scatter it with the hindlimbs. Burrows are simple,

Figure 22. Behavioural characteristics of *Jaculus jaculus*.

- (a) movement on all fours;
- (b) medium speed;
- (c) fast speed;
- (d) high jump;
- (e) sleeping;
- (f) sitting submissive;
- (g) standing alert;
- (h) washing rump;
- (i) cleaning tail;
- (j) sandbathing;
- (k) social contact between three jerboas;
- (l) pushing sand with nose (after Happold 1967a).

usually with two entrances, and vary in depth according to season; at Khartoum, winter burrows are shallow (20–25 cm deep with almost horizontal passages, and in summer, burrows are deeper (70–75 cm) with steeply sloping passages (Ghobrial & Hodeib 1973). After an individual has entered its burrow, the entrance is plugged from the inside with sand so that the entrance is practically invisible. Small sleeping chamber at base of burrow is lined with grass. Temperature and relative humidity in the burrow is relatively constant (temperature 26–28 °C in cool season when air temperature is 5–27 °C, and 37 °C in hot season when air temperature is 28–46 °C; humidity 60–100%) and does not experience the temperature or humidity fluctuations of the sand surface.

Skull has enlarged zygomatic plates, which protect the orbits when anterior part of head is used for pushing sand. Auditory bulla is large (ca. 40% of GLS) and greatly inflated; it assists detection of vibrations in sand when animal is in the burrow, and airborne sounds when it is on the surface.

Lesser Egyptian Jerboas can obtain all their water from their food (but will lick dew and standing water when available), and possess many special anatomical and behavioural features for conserving water. The kidney produces only small amounts of extremely concentrated urine (4320 mMol/l), about double the maximum concentration produced by a white rat. In experimental conditions, without free water and feeding on barley, an individual lost ca. 30% of body weight after three weeks (Schmidt-Nielsen 1964). In this respect, these jerboas are not as well adapted to lack of water as some other species of desert rodents (e.g. some *Gerbillus* and *Meriones* spp.). Other ways to reduce water loss and energy loss include nocturnal activity, resting in relatively cool and moist burrows, sleeping curled in a ball to reduce water loss from the lungs, feeding on foods with high water content when available (moist vegetation, bulbs) and seasonal changes in activity (Happold 1967a). In cool weather, Lesser Egyptian Jerboas rest in their burrows curled into a tight ball, tucking the head close to the abdomen and covering the long hindlimbs with the body; activity above ground is greatly reduced. In hot weather, they rest with legs and tail stretched away from the body, and sometimes lick saliva on to the fur to increase heat loss.

Foraging and Food Foraging takes place only at night, when seeds and stems are collected from the substrate with short forelimbs. Lesser Egyptian Jerboas sit in a crouched position while eating, with the whole length of the cannon bone resting on the ground, and the food is held with the forelimbs. Near Khartoum (and presumably elsewhere) the diet consists of small seeds, dried desert grasses and roots, as well as bulbs and corms in the dry season. Sometimes the fleshy leaves of some succulent plants are also eaten. After rainfall, Lesser Egyptian Jerboas feed on newly germinated grass sprouts. Their weak jaws prevent them from feeding on large hard seeds. There is no evidence that these jerboas collect and store food (cf. *J. orientalis* and many species of *Gerbillus*).

Social and Reproductive Behaviour In the desert, Lesser Egyptian Jerboas are seen singly (or occasionally in pairs or trios). They show many of the behavioural characters of solitary species: agonistic behaviour (fighting, chasing) when confined with an unfamiliar individual; a tendency to nest alone and to have limited

interactions with other individuals. In an established group, members show tolerance towards each other. No information available on reproductive behaviour.

Reproduction and Population Structure Reproduction is seasonal. Near Khartoum, young individuals were found from Sep to Dec, and in Feb and Mar (1964–66); this suggests two periods of pregnancies, one in Jun and Jul during the annual ‘wet season’ (average 150 mm/year), and the second in Oct–Dec when monthly temperatures are declining and food is still relatively abundant (Happold 1967a). In other years (1970–72), reproduction was almost continuous with peaks in Sep–Nov and Dec–Feb (Ghobrial & Hodeib 1973). Reproduction is probably opportunistic, and dependent on availability of nutritive food (and hence rainfall). Gestation: 44–46 days. Litter-size/number of embryos (regardless of season): 3.4 (2–5, mode 3, $n = 18$; Happold 1967a). Mean litter-size at Khartoum varies according to season: 4.8 in Sep (end rains, food abundant), 3.0 in Dec (cool temperature, food less abundant) and 1.83 (Jun, hot temperatures, food scarce) (Ghobrial & Hodeib 1973). Young born naked; development is slow for a rodent of this size: hair develops by Day 22; eyes open Day 38. Hindfoot and auditory bullae develop rapidly, reaching adult size quicker than other structures. At birth, cannon bone formed of three separate metatarsal bones, each 9 mm in length; at Day 40, bones fused and 50 mm in length, but unable to support weight of body. Weight when first active above ground ca. 20 g (= 35% adult weight, age 50–60 days) (Happold 1970a).

The relative age of an individual can be estimated by the wear on the cheekteeth: youngest animals are Age-class 3 (least wear on molars) and oldest animals are age-class 17 (maximum wear) (Happold 1967a). At Khartoum, in Sep–Dec (1964–66), after the rains and the first breeding period, there were individuals of all age classes, suggesting three age-groups: (a) age-classes 3–8, weight <40 g, born previous Jun–Jul, age 3–6 months; (b) age-classes 5–10, wt >40 g, born previous Oct–Dec, age 9–12 months; and (c) age-classes 10–17, wt >40 g, age more than 12 months. By Jan–Mar, most of the individuals in age-group (a) had moved to age-group (b), and many of the oldest individuals in age-group (c) had disappeared from the population. (No detailed information for Apr–Aug.) Individuals of age-classes 14–17 may be 3–4 years of age. Only 25% of individuals attained an age-class of 10 or above (Happold 1967a).

Predators, Parasites and Diseases Remains of Lesser Egyptian Jerboas have been found in owl pellets in Algeria (Kowalski & Rzebik-Kowalska 1991) and they are likely to be preyed upon by owls in many parts of their geographic range. In Egypt, they are hosts to many species of fleas, the commonest being *Xenopsylla nubica*, *X. cheopis* and *Synosternus cleopatrae*; none is specific to *J. jaculus* and are found also on other small rodents. Infection rate is low; infested individuals typically host 3–4 fleas (Hoogstraal & Traub 1965b). The blood parasite *Hepatozoon balfouri* infected 41% of jerboas examined in Egypt ($n = 370$) as well as many other species of Egyptian small mammals (Hoogstraal 1961).

Conservation IUCN Category: Least Concern.

The wide distribution of Lesser Egyptian Jerboas, and the sparseness of humans in their habitats, suggest that they are not threatened.

Jaculus orientalis GREATER EGYPTIAN JERBOA (ORIENTAL JERBOA)

Fr. Gerboise Orientale; Ger. Orientalische Springmaus

Jaculus orientalis Erxleben, 1777. Syst. Regn. Anim. 1: 404. 'In the mountains separating Egypt from Arabia' (= Egypt).

Taxonomy Several subspecies have been described (*orientalis*, *gerboa*, *mauritanus*) but none is recognized by Corbet (1978). This species was referred to (incorrectly) as *Dipus aegyptius* by Kirmiz (1962). The 'Desert Rats' of the North African campaign in World War II were named after this species. Synonyms: *bipes*, *gerboa*, *locusta*, *mauritanicus*. Subspecies: none. Chromosome number: not known.

Description Medium-sized jerboa with large rounded head, extremely long hindlimbs and very long tufted tail. Dorsal pelage brownish-orange, becoming paler on flanks; hairs grey at base, orange-brown on terminal half, sometimes with black tip. Ventral pelage pure white. Very similar in general characters to *J. jaculus*. Hindlimbs, especially metatarsal bones, very long (ca. 51% of HB); three hind digits well covered on undersurface with whitish bristles. Forelimbs short. Tail very long (ca. 146% of HB), ending with large tuft, black at base and white at tip. Nipples: not known.

Geographic Variation None recorded in Africa.

Similar Species

J. jaculus. Considerably smaller (e.g. HB: 98–118 mm; HF: 56–66 mm); widespread in desert habitats.

Allactaga tetradactyla. Considerably smaller but with longer ears (37–43 mm), four hind digits including short Digit 5 on outside of cannon bone; coastal regions Libya and Egypt only; rare.

Distribution Mediterranean Coastal BZ and coastal regions of Sahara Arid BZ in Libya and Egypt. Recorded from Morocco, Algeria and Tunisia, and the high plateaux of E Morocco and Algeria south to about 34°S, and in the regs and hamadas near the coast from W Libya to Egypt west of the Nile Delta. Prefers more humid environments to *J. jaculus* and does not extend southwards into the Sahara Desert. Also recorded from Sinai and S Israel. The geographical range overlaps with that of *J. jaculus* in a few areas of Algeria, Libya and Egypt.

Habitat Salt marshes with *Salicornia* bushes; limestone slopes covered by *Suada* bushes above the salt marshes; coastal dunes; gardens, meadows, olive growths and old barley fields covered with annual plants (Osborn & Helmy 1980). Compared with *J. jaculus*, these jerboas live in habitats that are less arid and have much more vegetation. Individuals found up to 1500 m on the High Atlas and Saharan Atlas mountains. Does not live in the sclerophyllous forests of Morocco, Algeria and Tunisia.

Abundance Very varied and dependent on food availability and character of the habitat. In Egypt, recorded as '1–50 jerboas per 0.8 km', and 'more or less common' on the desert slopes near the Mediterranean Sea from Egypt west of the Nile Delta to Libya and Algeria (Hoogstraal 1963). In Algeria, common on the high plateaux (Kowalski & Rzebik-Kowalska 1991).

Adaptations Terrestrial and nocturnal; similar in many ways to *J. jaculus* but confined to the Mediterranean coastal regions and hence less well adapted for desert environments. Greater Egyptian Jerboas have two main forms of locomotion: a bipedal hop with asynchronized foot support (rather like a gallop), and a bipedal trot, which is used for moving around and through bushes and shrubs (cf. *J. jaculus*) (Schröpfer *et al.* 1985).

Jaculus orientalis

Burrows usually 1–2 m in length, dug in hard ground, often on the slope of a hill (Kirmiz 1962). Burrow ends in a nest chamber lined with camel hair, shredded pieces of cloth or shredded vegetation. Some burrows have a food chamber (see below). Position of burrows changes seasonally: higher on hillsides during winter rains, and on lower ground close to fields in summer. When occupied, burrows are blocked with plugs of sand.

Water conservation has been measured by the percentage of body water that is 'turned over' in 24 h, and the volume and concentration of the urine. In cold conditions ($T_a = 8^\circ\text{C}$), water turnover (regardless of food) is ca. 10%/24 h, and in hot weather ($T_a = 32^\circ\text{C}$), it is reduced to 5%/24 h (when fed only on barley) and 9%/24 h (when fed on barley and 'salad'). Greater Egyptian Jerboas are able to produce small amounts of concentrated urine when required. For example, when fed on barley and 'salad', at $T_a = 8^\circ\text{C}$, urine production was 8.7 ml urine/24 h with an osmotic concentration of 714 mOsm/L, and at $T_a = 32^\circ\text{C}$ they produced 0.6 ml/24 h with an osmotic concentration of 2227 mOsm/L (Baddouri *et al.* 1985). In these respects, this species of jerboa is not as efficient at water conservation as *J. jaculus*.

In the winter, on parts of Mediterranean coast and high plateaux, air temperatures at night may be below freezing although the temperature in burrows is ca. 10°C . On the high plateaux of Morocco (1500 m), Greater Egyptian Jerboas taken from burrows in winter were immobile, breathing was spasmodic and body temperature was $10\text{--}11^\circ\text{C}$. On exposure to an air temperature of 17°C , shivering commenced and body temperature gradually increased to normal in ca. 4 h. Thus Greater Egyptian Jerboas show true hibernation, and are able to rewarm using endogenous mechanisms (El Hilali & Veillat 1975). They appear to be more tolerant of cold than Common Jerboas (Hooper & El Hilali 1972).

Foraging and Food Foraging is similar to that in Lesser Egyptian Jerboas but because of their large size, Greater Egyptian Jerboas are able to consume larger seeds. Food is mainly sprouting vegetation, plants, roots and barley grains (Kirmiz 1962). Various succulent shrubs such as *Salicornia* and *Suada* may be browsed by individuals inhabiting salt marshes (Osborn & Helmy 1980). Dates, barley and the seeds of several wild plants have been found in burrows.

Social and Reproductive Behaviour Sociable, and not usually encountered as solitary individuals (cf. *J. jaculus*) (Osborn & Helmy 1980). Parapatric (and perhaps syntopic) with *Allactaga tetradactyla* on the coasts of Libya and Egypt.

Reproduction and Population Structure Limited information. In Egypt, breeding occurs during winter (Nov–Feb) and summer, and less frequently during spring (Hoogstraal 1963). Births recorded in Feb, Apr and early Jul. Litter-size: 3, 4, 7 in Algeria (Kowalski & Rzebik-Kowalska 1991); 2, 3, 4, 5 (mode 3) in Egypt (Flower 1932).

Predators, Parasites and Diseases Remains found in owl pellets in Algeria (Kowalski & Rzebik-Kowalska 1991). In Egypt, a flea *Mesopsylla tuschkan* is found commonly in nests and on animals; nine other species of fleas have been recorded occasionally (Hoogstraal & Traub 1965b).

Conservation IUCN Category: Least Concern.

| <i>Spalax</i> (1 species) | Ehrenberg's Mole-rat | p. 145 |
| <i>Tachyoryctes</i> (2 species) | Root-rats | p. 148 |

This small family (six genera and 36 species) represents an old lineage of Muroidea whose extant members have acquired striking fossorial adaptations and evolved into predominantly subterranean niches. There are four subfamilies: Myospalacinae (Zokors), Rhizomyinae (Bamboo-rats), Spalacinae (Blind Mole-rats) and Tachyoryctinae (African Root-rats). The first two subfamilies are extralimital to Africa, myospalacines occurring in Siberian Russia and northern China, and rhizomyines in north-eastern India, southern China and the Malay Peninsula. The latter two subfamilies, the spalacines (one genus, one species) and tachyoryctines (one genus, two species), are geographically localized within Africa. The only African species of *Spalax* is found along the Mediterranean coastal region, and the two species of *Tachyoryctes* live in the highlands of Ethiopia and East Africa. Although each subfamily is readily diagnosed by unique traits (Carleton & Musser 1984), underground life in burrows has entailed the evolution of a suite of morphological, physiological, sensory and behavioural specializations common to subterranean forms in other rodent families and suborders (Nevo 1979, 1999, Nevo & Reig 1990, Lacey *et al.* 2000). General characters of Spalacidae include a cylindrical body shape with broad head and massive cervical musculature; very soft and fine pelage; small or vestigial pinnae and eyes; short or inconspicuous tail; short, stocky limbs and powerful appendicular musculature; enlarged claws, especially on the forelimbs; hypertrophy and procumbency of the lower incisors for chisel-tooth digging; and robust, hypsodont molars associated with their largely herbivorous diet of roots, bulbs and rhizomes (Carleton & Musser 1984, Stein 2000). Dental formula: $I^{1/1}$, $C^{0/0}$, $P^{0/0}$, $M^{3/3} = 16$ (Table 15).

Whether such phenotypic resemblance connotes phylogenetic relationship or evolutionary convergence, it has accounted for most of the differences in the classification of these rodents. Most taxonomic arrangements, implicitly or explicitly, reflect the view that the similar fossorial adaptations have evolved in parallel and have variously grouped the six genera within three or four separate subfamilies and in one to three families (see Topachevskii 1969, Carleton & Musser 1984 for reviews). In the prevalent classificatory treatment, Spalacidae and Rhizomyidae (including *Tachyoryctes*) have been retained as small outlying families separate from core Cricetidae and/or Muridae (e.g. Miller & Gidley 1918, Ellerman 1940, Simpson 1945, Pavlinov *et al.* 1995). Some palaeontologists have echoed a similar viewpoint and have considered that Spalacidae and Rhizomyidae (a non-African taxon) originated independently from different muroid stocks (Flynn *et al.* 1985).

As early as 1899, however, Tullberg interpreted their shared resemblance as phylogenetic relationship and placed *Myospalax*, *Spalax*, *Rhizomys* and *Tachyoryctes* in Spalacidae, separate from his Cricetidae and Muridae. Monophyletic union of these fossorial genera has earned substantial support from recent studies, including evidence from morphology of the cephalic arterial system (Bugge 1971, 1985) and repeatedly from phylogenetic reconstruction based on nuclear gene sequences (Robinson *et al.* 1997, Debry & Sagel 2001, Michaux *et al.* 2001, Jansa & Weksler 2004). These data collectively portray myospalacines, rhizomyines, spalacines and tachyoryctines as a clade (Spalacidae) that is a sister-group to representatives of all other muroid families so far investigated (Calomyscidae, Cricetidae, Muridae, Nesomyidae) and infer an early divergence (and possibly one of the earliest divergences) of Spalacidae within Muroidea from a middle or late Oligocene ancestral stock.

Table 15. Subterranean rodents in Africa.

| Family: genus | Number of upper cheekteeth | Upper cheektooth row | Upper incisor teeth | Infraorbital foramen | Eyes | Tail |
|---|---|----------------------|--|-------------------------------------|-------------------------|---|
| Spalacidae: <i>Spalax</i> | 3 (M^1 , M^2 , M^3) | Diverge anteriorly | Orthodont, ungrooved, not extrabuccal | Large, well developed | Absent (non-functional) | Absent externally |
| Spalacidae: <i>Tachyoryctes</i> | 3 (M^1 , M^2 , M^3) | Converge anteriorly | Pro-odont, ungrooved, slightly extrabuccal | Large, well developed | Very small | Short, visible externally (20–30% of HB); well haired |
| Bathyergidae: <i>Bathyergus</i> | 4 (P^4 , M^1 , M^2 , M^3) | Parallel | Pro-odont, grooved, strongly extrabuccal | Very small, round | Small | Short, visible externally (18–24% of HB); stiff bristles |
| Bathyergidae: <i>Heliophobius</i> | 6 (but usually 4 or 5; left side may differ from right) | Parallel | Pro-odont, grooved, strongly extrabuccal | Very small, round | Small | Very short, visible externally (9% of HB); stiff bristles |
| Bathyergidae: <i>Heterocephalus</i> | 3 (sometimes 2) | Parallel | Pro-odont, ungrooved, strongly extrabuccal | Very small, round | Very small | Moderately long (ca. 50% of HB); naked |
| Bathyergidae: all genera except <i>Heterocephalus</i> | 4 (P^4 , M^1 , M^2 , M^3) | Parallel | Pro-odont, ungrooved, strongly extrabuccal | Small, teardrop or elliptical shape | Small | Short, visible externally (7–18% of HB), stiff bristles |

Although Oligocene fossils are so far unknown, the documented fossil history of Spalacidae is suitably deep in time to be consistent with a middle to late Oligocene origin. The earliest indisputable records among the four subfamilies are early Miocene, around 19–20 mya in Asia Minor (*Debruijnina*, Spalacinae) and southern Asia (*Prokanisamys*, Rhizomyinae) (see Flynn 1990, Nevo 1999 and Cook *et al.* 2000 for palaeontological summaries). In Africa, the earliest occurrences of the family originate from middle to late Miocene strata of Kenya (as *Pronakalimys* and *Nakalimys*; Flynn & Sabatier 1984, Tong & Jaeger 1993) and the late Miocene of Namibia (as *Nakalimys* and *Harasibomys*; Mein *et al.* 2000a). Although dental contrasts between living spalacid genera are highly distinctive, it is noteworthy

that molar similarities among certain African Miocene forms render assignment to subfamily – whether rhizomyine, spalacine, or tachyoryctine – as indefinite (Mein *et al.* 2000a). Spalacids were more geographically widespread and taxonomically diverse during the late Miocene through Pliocene (see Flynn 1990, Ünay 1999, Cook *et al.* 2000), a comparison that reinforces the impression that the relatively few extant spalacids, so strongly differentiated from one another, are relicts from a much older muroid radiation.

Two subfamilies of Spalacidae occur in Africa: Spalacinae (1 genus, 1 species) and Tachyoryctinae (1 genus, 2 species).

Guy G. Musser & Michael D. Carleton

Subfamily SPALACINAE – Mole-rats

Spalacinae Gray, 1821. London Med. Repos. 15: 303.

The Spalacinae encompasses a single living genus, *Spalax*, whose range stretches from SE Europe and SW Asia around the Black and Caspian Seas, through Asia Minor and the near Middle East, to North Africa (see Nevo *et al.* 2001). The recent distribution broadly follows the hilly, uplifted region that corresponds to the ancient basin of the Mediterranean Sea and is generally concordant with that of known spalacine fossils (Ünay 1999). Conventionally, eight living species of *Spalax* are recognized (e.g. Topachevskii 1969, Musser & Carleton 1993), but this number may grossly underestimate the specific diversity (see later). Only a single species, *S. ehrenbergi*, occurs in Africa; its distribution is limited to the Mediterranean coastal region

of W Egypt and Libya (Lay & Nadler 1972). As currently understood, these North African populations are separated from those of *S. ehrenbergi* in the southern Levant by the Nile Delta and arid Sinai Desert (rainfall <100 mm).

The pronounced fossorial modifications exhibited by *Spalax* readily separate it from other African Muroidea, including *Tachyoryctes* (Tachyoryctinae, see below), the only other African representative of Spalacidae. The eyes, pinnae and tail are externally lacking in *Spalax*; bristly, facial hairs form stiff lateral keels and impart a wedge-like shape to the head; claws of fore- and hindfeet are enlarged; the occiput is slanted and the lambdoidal crest is shifted forward, forming a large occipital shield for insertion of cervical musculature; rear of glenoid fossa is enclosed by a bony wall that enlarges the occipital shield; the interparietal is undefined in adults; the jugal is short and thin; the infraorbital foramen is wide and ovoid, with the zygomatic plate narrow and nearly horizontal; mesopterygoid fossa U-shaped ending anteriorly in line with posterior end of third molars; roof of parapterygoid fossa open; upper incisors are orthodont and the lowers long and procumbent, the maxillary tooththrows parallel to one another; olecranon process for insertion of triceps brachii is elongate, about two-thirds the length of the main shaft of the ulna (Topachevskii 1969, Carleton & Musser 1984, Hildebrand 1985) (Figure 23). In contrast to *Tachyoryctes*, many traits of *Spalax* indicate that it is more highly specialized for subterranean living, differences that agree with its rare surface-foraging as compared with *Tachyoryctes*.

In view of its many autapomorphies, *Spalax* has been commonly classified in a family by itself (Ellerman 1940, Simpson 1945, Topachevskii 1969, Nevo 1999) or variously with other similarly adapted fossorial muroids, especially rhizomyines and tachyoryctines (Thomas 1897, Tullberg 1899). Recent phylogenetic evidence persuasively supports the latter relationship and cladistically arrays spalacines with such groups in a basal lineage (Spalacidae) of Muroidea (see family profile). Divergence times based on nuclear gene sequences estimate the separation of spalacines from other muroids as about 19 mya (Robinson *et al.* 1997, Michaux & Catzeflis 2000), an origin consistent with the antiquity of the earliest spalacines so far documented.

The oldest spalacine genera are recorded about 18–20 mya (*Debruijnina* and *Heramys* from the early Miocene of Turkey and Greece, respectively), and the speciose *Pliopspalax* is known from the middle

Figure 23. Skull and mandible of *Spalax ehrenbergi* (RMCA no number).

Miocene–Pliocene in Asia Minor and middle Miocene–early Pleistocene in Europe (see reviews by Ünay 1996, 1999, Kowalski 2001). Because fossorial adaptations already characterize Miocene *Pliospalax* (Sen 1977), spalacines are believed to have evolved into a fossorial and subterranean niche around 14–15 mya, much earlier than either tachyoryctines or rhizomyines (Flynn 1990). Living *Spalax* is a descendant of this once extremely diverse group, one thought to have originated and diversified in Anatolia (Ünay 1999). The genus itself appears in the early Pliocene of Europe and middle Pleistocene of SW Asia (Topachevsky *et al.* 1998, Ünay 1999, Kowalski 2001), and the *S. ehrenbergi* complex in Israel dates from at least 1.4 mya (Nevo 1995, Tchernov 1996). The North African segment of *S. ehrenbergi* was isolated relatively recently, separating from Levant populations only about 10,000 to 20,000 years ago (Lay & Nadler 1972, Nevo *et al.* 1992), perhaps coincident with the disjunction of *Microtus mustersi* in the same region.

The number of genera and species considered to be valid are subjects of continuing research. A single genus had been identified in most systematic accounts (e.g. Ellerman 1940, Ognev 1947) until Topachevskii (1969) recognized two genera, *Spalax* and *Microspalax* (= *Nannospalax*), based on subtle cranial and dental differences.

Although the dual generic arrangement gained acceptance in the late 1900s (e.g. Musser & Carleton 1993, Gromov & Erbaeva 1995, Mitchell-Jones *et al.* 1999), specialists on Blind Mole-rats continue to endorse only the single genus *Spalax* (Savic & Nevo 1990, Ünay 1996, 1999, Nevo *et al.* 2001), a taxonomy based more on expediency rather than firm understanding of supraspecific relationships. Based on morphological criteria, seven or eight living species have been usually recognized (Ognev 1947, Topachevskii 1969). None the less, the extraordinary variation in diploid and fundamental numbers ($2n = 38–62$, $FN = 72–124$) uncovered within *Spalax* has prompted some investigators to consider many of these morphological entities as superspecies, with the distinct chromosomal morphs representing as many as 30 to 50 biological species (Savic & Nevo 1990, Nevo *et al.* 1995). Populations in Egypt and Libya are members of the *S. ehrenbergi* superspecies (*sensu* Nevo 1991, Nevo *et al.* 2001). If these are treated as a separate species, as suggested by Nevo *et al.* (1992), then *aegyptiacus* is the name that should be applied to this North African segment of the *S. ehrenbergi* complex.

Guy G. Musser & Michael D. Carleton

GENUS *Spalax*

Mole-rats

Spalax Guldenstaedt, 1770. Nova Comm. Acad. Sci. Petropoli, ser. 14, 1: 410. Type species: *Spalax microphthalmus* Guldenstaedt, 1770.

Spalax ehrenbergi.

The genus *Spalax* contains eight species, of which only one is represented in Africa. The characters of the genus are given in the profile Subfamily Spalacinae (above) and the species profile (below). The single African species, *Spalax ehrenbergi*, was placed in the genus *Nannospalax* by Musser & Carleton (1993).

Spalax ehrenbergi MIDDLE EAST BLIND MOLE-RAT (EHRENBERG'S MOLE-RAT)

Fr. Spalax d'Ehrenberg; Ger. Ehrenberg-Blindmaus

Spalax ehrenbergi (Nehring, 1898). Sber. Ges. Naturf. Freunde Berlin 1897, p. 178. pl. 2. (publ 1898). Jaffa, Israel.

Taxonomy The Egyptian form described as *S. aegyptiacus* is now considered as junior synonym of *S. ehrenbergi*. Genetics, karyology, physiology, behaviour, adaptive radiation and evolution of the species has been extensively studied in Israel, although the definition and limits of the species are still uncertain (see Spalacinae). Considerable karyotypic variation: $2n$ may be 52, 54, 58 or 60, the highest $2n$ number being in populations from the most arid regions. Alternatively, according to Nevo (1991; details in Musser & Carleton 2005), 'ehrenbergi' in Israel may be considered as four parapatric species (*S.*

carmeli, *S. galili*, *S. golani*, *S. judaei*), each with different chromosome numbers and morphological traits (recent studies in Israel have referred to these four species as the '*S. ehrenbergi* superspecies'). African populations have the same number of chromosomes as those from arid regions of Israel, but can be distinguished by baculum morphology (Simson *et al.* 1993), cranial morphology (Ellerman & Morrison-Scott 1951) and molar variation (Butler *et al.* 1993). They may have evolved independently from populations in Israel (and the Middle East) as a result of long-term isolation imposed by the arid

conditions in the Sinai Desert (Nevo *et al.* 1992); if so, *S. aegyptiacus* is the correct name for the African populations (Musser & Carleton 2005). Synonyms: *aegyptiacus*. Subspecies: none. Chromosome number: $2n = 60$ (Egypt; Lay & Nadler 1972).

Description Large subterranean species with cylindrical shape and without visible tail. Pelage soft and silky, dense; hairs ca. 10 mm. Dorsal pelage greyish-brown with silvery sheen; hairs dark grey with pale brown or orange-brown at tip. Ventral pelage dark grey; hairs dark grey at base with or without pale brown or orange-brown tip. Head blunt and rounded; hairs pale, may be almost white, on anterior part of head. Eyes small and vestigial, permanently covered by skin. Rhinarium hairless, but with longer hairs on muzzle and upper lips. Incisors slightly extrabuccal. Ear pinnae reduced to small cartilaginous ring surrounding auditory meatus. Forelimbs short, same colour as body. Forefeet broad with five digits; Digit 1 shorter than Digits 2–5; short rounded claws. Hindfeet not broadened; five digits; Digits 1 and 5 short reaching only to base of Digits 2, 3 and 4. Tail very short, not visible externally. Skull: upper incisor teeth ungrooved; orthodont to slightly pro-odont; braincase triangular in shape; supraoccipital bone very large, slopes anteriorly so that lamboid crests are in line with end of zygomatic arches. On mandible, lower incisor teeth very long; well-developed alveolar and angular processes, in addition to the condylar process (Figure 23). See also profile Subfamily Spalacinae.

Geographic Variation In Libya, individuals on the Cyreniaca Plateau are smaller than those near the coast, perhaps because the soils of the plateau are harder and less sandy than those of the coast; hence burrowing is more difficult, and small size is advantageous (Ranck 1968). Pelage colour varies locally depending on soil colour (Nevo 1991).

Similar Species This is the only subterranean species in its geographic range, and the only species that has vestigial eyes. Body

shape bears resemblance to other subterranean rodents (e.g. *Tachyoryctes*, *Heliophobius*, *Cryptomys*, etc.) but all are allopatric to *S. ehrenbergi*.

Distribution Sahara Arid BZ. Recorded from coastal regions of Libya (Cyreniaca region) and Egypt (west of the Nile Delta). Not recorded further west, i.e. not recorded from Algeria (Kowalski & Rzebik-Kowalska 1991). Extralimittally present in Israel, Lebanon, Jordan, Syria and SW Turkey.

Habitat Soil quality and texture determine distribution. Preferred habitats in Egypt include deep sandy and loamy soils where *Asphodelus microcarpus* is the commonest plant, and fields of barley (Osborn & Helmy 1980). In Libya, recorded in fertile soils in valleys, on coastal plains and on the uplands of Cyreniaca Plateau (Ranck 1968). Prefers habitats where annual rainfall is 100–300 mm. Avoids areas where flooding may occur, rocky areas and areas of extreme aridity (annual rainfall <100 mm).

Abundance Populations are localized because of subterranean life-style and the difficulties of dispersal (see below). In optimal habitats in Israel, mean density was 3 individuals/1000 m² (range 0.6–6.1; Nevo 1982, in Heth 1991a). No information on abundance in Africa, although said to be widespread in coastal parts of Libya after rains (Ranck 1968). Probably less common in Africa than in some parts of the Middle East.

Adaptations Probably the most adapted of all rodents to subterranean life. Body shape is cylindrical, with wide blunt head, short powerful limbs and no tail. Unlike other subterranean rodents, the eye is atrophied and covered by a thick layer of skin (hence an external eye is not visible), and the orbits are filled with a gland, which produces secretions that are thought to reduce aggression during encounters with conspecifics (Shanas & Terkel 1995). Perception of light is very limited or non-existent. Burrows vary in length and depth: in Egypt, they are 30–40 m in length and ca. 45 cm below the surface (Osborn & Helmy 1980); in Israel, they are 20–40 cm below the surface and vary in length according to season, from 18.7 ± 4 m in the dry season to 39.1 ± 7.1 m in the wet season (Zuri & Terkel 1996). Typical burrows consist of a main tunnel, with multiple secondary tunnels, and two or more entrances. The large incisor teeth cut and scrape the soil during burrowing, the blunt head pushes and packs the soil within the burrow, and the fore- and hindlimbs push the loosened soil behind the body. Excavated soil is pushed into mounds on the surface; these are the most visible signs of Blind Mole-rats, and are especially visible when there is increased burrowing activity after rain. Burrows contain food-stores, toilets and nests; normally there are several nests, but only one is used at a time (Heth 1991a). Entrances to burrow are normally plugged with soil (Ranck 1968).

Although living underground (where daily variations in temperature are minimal, and it is dark all the time), Blind Mole-rats have peaks of locomotor activity from 08:00h to 11:30h during summer, and 11:00 to 19:00h during winter. It seems that brief light pulses perceived through the rudimentary eyes when pushing soil at the surface are an adequate stimulus to entrain a diurnal rhythm of activity (Goldman *et al.* 1997). Most burrowing activity occurs

during the wet season in winter and spring, and the least activity during the hot and dry summer (Osborn & Helmy 1980).

Ehrenberg's Mole-rats do not drink free water; rather they rely on water in the diet (see below).

Foraging and Food Herbivorous. Forages while digging 'feeding tunnels'; these usually form most of the burrow system. The main items in the diet are corms, bulbs, tubers, fibrous roots and rhizomes of those plant species that specialize in underground storage organs (Heth 1991a). Food items may be collected and hoarded in food stores. Analysis of 21 food stores in Israel showed many hundreds of items may be stored comprising at least 33 species of plants; these include the underground parts of geophytes (61%), perennial herbs (21%), annual herbs (15%) and dwarf shrubs (3%) (Heth *et al.* 1989). Blind Mole-rats are generalists feeders, utilizing many species of plants, probably because of the high energy requirements of burrowing and the low productivity of their subterranean environment (Nevo 1991). A further adaptation to low productivity is the relatively large caecum, with a spiral valve (as in rabbits) that doubles the absorptive surface area (Nevo 1991). Potatoes, carrots and onions are collected and eaten in cultivated areas.

Social and Reproductive Behaviour Solitary, aggressive and territorial. Normally only one individual inhabits each burrow system, where it lives for all its life (Heth 1991a). The burrow system is marked by deposits of urine and faeces. Blind Mole-rats use vibrations (produced by 'head drumming') to communicate with mole-rats in adjacent burrow systems (Zuri & Terkel 1996). Young disperse when ca. two months old; it burrows away laterally from the maternal burrow and, when ca. 4 m away, seals the burrow behind it and establishes its own territory (Rado *et al.* 1992). In dense populations, some young disperse above ground.

Reproduction and Population Structure In Israel, reproduction occurs during the cool winter season (Nov–Apr), but later at higher altitudes in Lebanon. Most births occur in Jan and Feb in Israel (Rado *et al.* 1992), but as late as Apr at higher

altitudes in Lebanon (Lewis *et al.* 1967). Gestation: 34 days. Litter-size: 2–3.

Predators, Parasites and Diseases Predation appears to be uncommon. Blind Mole-rats are preyed upon occasionally by Barn Owls *Tyto alba* in Israel. They formed 0.4% of the rodents and shrews in 1023 owl pellets from seven localities in Israel (Heth 1991b); all were juveniles or subadults, presumably caught above ground while dispersing. No fleas were found on these mole-rats, nor in their burrows, in Egypt ($n = \text{ca. } 100$ animals/burrows; Hoogstraal & Traub 1965b), possibly because the environment in burrows is too damp for fleas. *Ctenophthalmus levanticus* and a few other fleas have been found on these mole-rats in Lebanon (Lewis 1964, quoted by Hoogstraal & Traub 1965b).

Conservation IUCN Category: Data Deficient (throughout range; no separate assessment for Africa). In Israel, regarded as a pest in agricultural crops and tree plantations.

Measurements

Spalax ehrenbergi

TL: 189.0 (163–203) mm, $n = 7$

T: ca. 15–16 mm (not visible externally)

HF: 25.0 (23–26) mm, $n = 7$

E: 0 mm

WT: 107, 120 g, $n = 2^*$

GLS: 44.2 (42.5–46.5) mm, $n = 6$

Subfamily TACHYORYCTINAE – African Root-rats

Tachyoryctinae Miller and Gidley, 1918. J. Wash. Acad. Sci. 8: 437.

The Tachyoryctinae consists of a single living genus, *Tachyoryctes*, that is endemic to highlands of north-eastern Africa and whose greatest taxonomic diversity is centred on the highlands and mountains of Kenya. Considerable fossil evidence, however, indicates that the subfamily once extended into southern Asia, as far as northern India (summaries in Nevo 1999, Cook *et al.* 2000), and perhaps into south-western Africa, as far as Namibia (Mein *et al.* 2000a).

Although largely subterranean in habits, *Tachyoryctes* is not so fossorially specialized as *Spalax*. Eyes, pinnae and tail are small but clearly visible in *Tachyoryctes*; pelage of the head is unmodified, and the claws of the fore- and hindfeet are unremarkable in size. Skull characters include occiput nearly horizontal, occipital shield relatively small, rear of glenoid fossa open, interparietal reduced but distinct, jugal long and deep, infraorbital foramen round above and constricted below with the zygomatic plate much broader and more

vertical, mesopterygoid fossa V-shaped ending anteriorly between the third molars, and roof of parapterygoid fossa wholly osseous. The upper and lower incisors are procumbent and the maxillary toothrows are convergent anteriorly (Figure 24). The olecranon process for insertion of triceps brachii is elongate, about one-third of the length of the main shaft of the ulna (Carleton & Musser 1984, Hildebrand 1985).

Although *Spalax* occurs nearby in North Africa and the Middle East, *Tachyoryctes* is thought to be most closely related to the Bamboo Rats (*Cannomys* and *Rhizomys*: Rhizomyinae) of southern China and South-East Asia. Most systematists have thus classified *Tachyoryctes* with those Asian genera, usually as a distinctive subfamily of Rhizomyidae on the basis of differences in dentition, infraorbital canal and zygomatic plate (Miller & Gidley 1918, Chaline *et al.* 1977, Flynn 1990), or unsegregated within Rhizomyinae of Muridae *sensu lato* (Carleton &

Figure 24. Skull and mandible of *Tachyoryctes splendens* (RMCA no number)

Musser 1984). Others, instead, have emphasized molar similarities between *Tachyoryctes* and the nesomyine *Brachyuromys* (Major 1897); classifications that reflect this interpretation of relationship have placed *Tachyoryctes* in its own subfamily within a broadly defined Muridae (Ellerman 1941) or Nesomyidae (Lavocat 1978). Palaeontological discoveries (Flynn 1982, 1990, Tong & Jaeger 1993) and phylogenetic evaluations of gene-sequence data (Michaux *et al.* 2001, Jansa & Weksler 2004) decisively reinforce close kinship of *Tachyoryctes* with Asian rhizomyines. The latter molecular studies

relate *Tachyoryctes* and *Rhizomys* as sister genera among those spalacids studied (also *Myospalax* and *Spalax*).

Tachyoryctines are documented by several extinct genera from the middle to late Miocene Siwalik faunas of Afghanistan, Pakistan and northern India (Black 1972b, Flynn 1982, 1990). As currently understood, tachyoryctines were more taxonomically diverse in those Miocene beds of south-western Asia than in comparably aged strata of Africa. In view of this past distribution and apparent cradle of early diversity, tachyoryctines are supposed to have originated in Asia and emigrated to Africa in one (>14 mya) or two stages, the last (ca. 5 mya) giving rise to *Tachyoryctes* (Flynn & Sabatier 1984, Flynn 1990, Tong & Jaeger 1993). The oldest record of *Tachyoryctes* proper is *T. pliocaenicus*, recorded from the late Pliocene (Hadar Formation) in Ethiopia (Sabatier 1978). Palaeontologists, however, are reluctant to definitely assign the earliest African forms – the middle Miocene *Pronakalimys* (Tong & Jaeger 1993) and late Miocene *Nakalimys* and *Harasibomys* (Flynn & Sabatier 1984, Mein *et al.* 2000a) – to subfamily, whether tachyoryctine or rhizomyine (Tong & Jaeger 1993) or even early spalacine (Mein *et al.* 2000). At this stage of understanding, the continental area of origin is equivocal. An alternative possibility, which merits consideration, is that the common ancestor of tachyoryctines and rhizomyines evolved in Africa, with subsequent dispersion (and cladogenesis) in Asia.

Morphological recognition of the genus is unproblematic, but how many of the 20 described forms of *Tachyoryctes* represent valid species remains unanswered. The number recognized has ranged from as many as 11–14 (Allen 1939, Ellerman 1941, Musser & Carleton 1993, 2005) to as few as two (Misonne 1974, Rahm 1980, Corbet & Hill 1991). Appreciation of the large morphological variation and acceptance of the polytypic species concept resulted in the abrupt reduction from 14 to two species in the latter 1900s. In view of the montane isolation among many tachyoryctine populations, and the re-emerging appreciation of diversity of other taxa distributed over East African Rift Mts, species recognition within *Tachyoryctes* should ultimately rest on some empirical framework instead of theoretical preconceptions. Until such evidence becomes available, the two conventional species, *T. macrocephalus* and *T. splendens*, are acknowledged here.

Guy G. Musser & Michael D. Carleton

GENUS *Tachyoryctes*

Root-rats

Tachyoryctes Rüppell, 1835. Neue Wirbelth. Fauna Abyssin. Gehörig., Säugeth: 35. Type species: *Bathyergus splendens* Rüppell, 1835.

The genus contains two species distributed in Ethiopia, Somalia, Kenya, Tanzania (Mt Kilimanjaro), Uganda, E DR Congo, Rwanda and Burundi. Found in a variety of habitats from forest to open grasslands at altitudes of above 1500 m (Ellerman 1940, Rahm 1980).

The body form is modified for subterranean existence: cylindrical head and body; short limbs; short tail (20–32% of HB); small ear pinnae closely applied to head; and small eyes. Pelage is thick and soft. Skull characters include conspicuously constricted frontals

(interorbital region); wide rostrum housing thick, orange, ungrooved incisors; long jugal bone almost reaching the lacrymal; narrow palate anteriorly, which broadens posteriorly with a prominent raised ridge running down the centre; and small anterior palatal foramina. Cheekteeth very hypsodont but rooted and with deep folds running across the teeth. Mandible with high recurved coronoid process and a prominent process (between condylar and angular) caused by the root of lower incisor (Ellerman 1940). See also profile subfamily Tachyoryctinae.

Tachyoryctes splendens.

African Root-rats are solitary aggressive animals living underground in a system of foraging burrows, where there is also a deep nest with associated toilet area, and a bolt-hole. They are exclusively herbivores, eating grasses, herbs and underground storage organs. Unlike the other subterranean rodents (Bathyergidae), root-rats forage both underground and on the surface. When foraging on the surface, root-rats keep their hindquarters in the hole, ready for rapid retreat, and hence foraging is limited to what can be reached

from the immediate vicinity of an open hole. They are chisel-tooth diggers but differ from the Bathyergidae in using one forelimb and the side of the face to push excavated soil onto the surface (Jarvis & Sale 1971). They also differ from the Bathyergidae in having better vision and small ear pinnae.

The number of species in the genus is uncertain; many species and a number of subspecies have been described but there is no clear consensus about the systematics of this genus. Musser & Carleton (1993, 2005) recognized 11 species, and Misonne (1974) and Corbet & Hill (1991) recognized only two (*T. splendens* and *T. macrocephalus*). Study of the 11 'species' from 53 locations throughout the range of the genus showed that most of the variation observed reflects adaptations to ecological conditions and hence there is no basis for the recognition of more than two species, *T. macrocephalus* and *T. splendens* (Beolchini & Corti 2004). Karyological and cytogenetic information is required to resolve these differences of opinion.

The two species are distinguished by size, width of the interorbital constriction, upper incisor width and geographic location.

J. U. M. Jarvis

Tachyoryctes macrocephalus GIANT ROOT-RAT (GIANT MOLE-RAT)

Fr. Rat-taupe géant d'Ethiopie; Ger. Riesen-Maulwurfsratte

Tachyoryctes macrocephalus (Rüppell, 1842). Mus. Senckenbergiana 3: 97, 115, pl. 8 fig 10 and pl. 10, fig 2. Shoa, Ethiopia.

Taxonomy Originally described in the genus *Rhizomys*. *Tachyoryctes macrocephalus* is clearly distinguished from its congener by its much larger size and different chromosome number. Synonyms: *hecki*. Subspecies: two. Chromosome number: $2n = 50$ (Aniskin *et al.* 1997b).

Description Very large, soft-furred root-rat (ca. 600 g) about three times the weight of *T. splendens*. Pelage soft, dense and long (up to 20 mm). Dorsal pelage pale brown; hairs dark grey at base, pale brown or buff at tip. Ventral pelage paler, silvery-grey to pale buff; hairs grey at base, pale buff at tip. Colour variable from silver to shades of orange. Head large; 1–3 dark brownish-black lines on crown of head (variable); dark spot on upper eyelid. Ears very small, held close to head, pigmented, with short hairs especially on outer margins. Limbs short. Fore- and hindfeet silvery-grey. Tail very short (ca. 20% of HB), thick at base with long hairs, tapering to tip with short hairs. Skull: interorbital width narrow (ca. 6–7 mm), large narrow extrabuccal incisors (size variable and useful for determining size, age and weight).

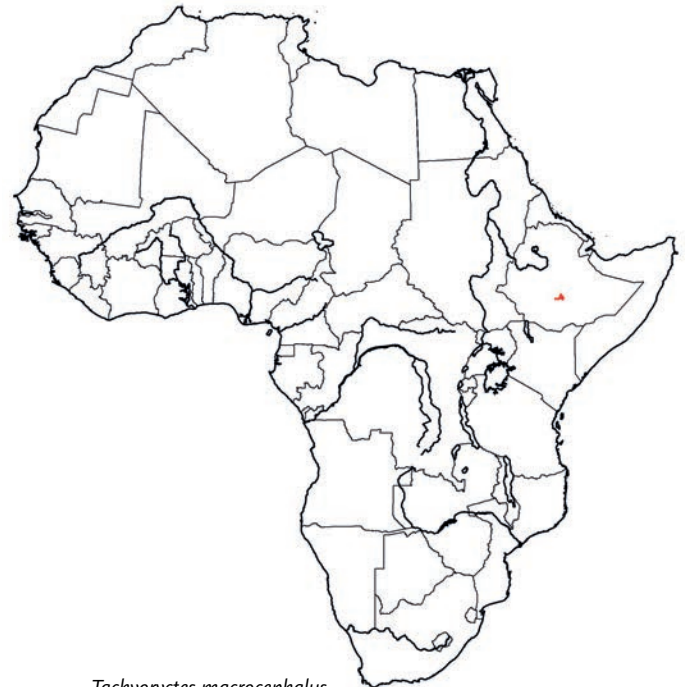

Geographic Variation

T. m. macrocephalus: N Ethiopia (only known from four specimens). Short anterior palatal foramina (ca. 5.0 [range 3.6–6.0] mm, $n = 4$); zygomatic plate angular.

T. m. hecki: Bale Mts, S Ethiopia. Longer anterior palatal foramina (ca. 8.5 [range 7.3–9.5], $n = 4$); zygomatic plate slopes down to the premaxillary–maxillary suture.

Similar Species

T. splendens. Smaller body size and weight (HB 159–215 mm, WT 140–315 g; wider interorbital width, absolutely and relatively (ca. 7 mm); more widespread in eastern Africa.

Tachyoryctes macrocephalus

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Confined to the high plateaux of Ethiopia, from 3000 to 4150 m. Known from Bale Mts east of the Rift Valley but apparently absent from nearby Arussi mountains. The type locality in N Ethiopia suggests that it occurs (or occurred) elsewhere, but the modern province of Shoa is nowhere high enough, and a locality in Wellu or Begemdir seems more probable (Yalden *et al.* 1976, Yalden & Largen 1992).

Habitat Highland grasslands and moorlands (Yalden 1988, Sillero-Zubiri *et al.* 1995a). In the Web Valley, Bale, most abundant in swamp shore grasslands, common in mixed herbaceous moorlands, but much scarcer in ericaceous scrub and rocky grasslands. Prefers soil depths over 50 cm (Sillero-Zubiri *et al.* 1995a). Often occurs with *Lophuromys melanonyx* and *Arvicanthis blicki*.

Abundance Common in its community, contributing to a tunnel-ridden landscape in which rodents, not plants, dominate the community (Yalden 1985, Miede & Miede 1994). Densities typically of 36/ha, but ranging from 90/ha in preferred habitats (Yalden 1975, Sillero-Zubiri *et al.* 1995a) to ca. 20/ha in less preferred habitats such as rocky grasslands and at lower altitude sites (Sillero-Zubiri *et al.* 1995a). Total rodent biomass in these communities may reach 26 kg/ha, of which this species contributes 50–60% (Sillero-Zubiri *et al.* 1995b).

Adaptations Subterranean and diurnal; activity begins around 08:00h and finishes by 16:00h; individuals visibly active at tunnel entrances for about ten bursts of activity totalling 60 min/day in the dry season, and slightly less in the wet season (Yalden 1975, Sillero-Zubiri *et al.* 1995a). Burrows are easily detected by mounds of earth on the surface; they are up to 90 m in length, with tunnels 12–15 cm in diameter below ground and 7.7 cm diameter at the entrance hole (Yalden 1975); burrows may cover an area of 360 m² (Shimelis Beyene 1986).

The eyes are placed high on the head (partly as a result of the narrow interorbital width), perhaps an adaptation for detecting predators in the open upland habitat (Yalden & Largen 1992). Root-rats make very rapid movements of the head upwards through earth mound (in order to detect potential danger), and then snatch grass and herbs near edge of mound; often accompanied by short squirrel-like squeaks (see also below). The large size (compared with other Ethiopian rodents), soft fur, diurnal habits and the habit of sealing the burrow system at night, are assumed to be responses to the low night-time temperatures at high altitude (Yalden 1975, Yalden & Largen 1992, Sillero-Zubiri *et al.* 1995a).

Foraging and Food Herbivorous. Feeds by opening a tunnel from below, gathering the available herbage within reach of the tunnel entrance while keeping the hindquarters inside the entrance. Each entrance hole is surrounded by bare ground to about 10 cm. When the food is depleted around one hole, the animal opens a new foraging hole, sealing the old one as it does so. Typically two holes are opened per animal/day, and these freshly used holes provide a good index of mole-rat density (Sillero-Zubiri *et al.* 1995a). Food is gathered in short bursts of 6–8 min at a time. The animal disappears below ground with each mouthful where (presumably) the food is consumed, thus minimizing exposure to predators. Principal foods are grasses and herbs, particularly *Festuca* and *Alchemilla*; roots and

tubers are not so important as for mole-rats (family, Bathyergidae) (Yalden 1975). Old nest material, food and faecal pellets are discarded periodically through a tunnel entrance resulting in ‘hay-piles’, another characteristic sign of this species.

Social and Reproductive Behaviour Little information. Appears to be solitary, and each animal occupies its own burrow system.

Reproduction and Population Structure Little information. Limited observations suggest ♀♀ produce only one young per litter. Juveniles weigh up to 300 g and form the majority of the prey of Ethiopian Wolves (see below); adults may increase in size throughout life, reaching a maximum of ca. 1000 g (Sillero-Zubiri *et al.* 1995a).

Predators, Parasites and Diseases Vulnerable to diurnal predators, especially Ethiopian Wolves (*Canis simensis*). Giant Root-rats contribute up to 47% by volume (69% by occurrence) of the diet of Ethiopian Wolves, and they are also preferred prey compared with other rodents in ‘cafeteria tests’ (Sillero-Zubiri & Gottelli 1995). Probably vulnerable to other diurnal predators, including raptors. Occasionally taken by owls (Yalden 1973).

Conservation IUCN Category: Endangered; formerly assessed as Vulnerable.

At present, sufficiently common and widespread, although the very limited range of the species is cause for concern. Giant Root-rats are very important to the dynamics of their ecosystem, and are an important food for the highly endangered Ethiopian Wolf (Miede & Miede 1994, Sillero-Zubiri *et al.* 1995a).

Measurements

Tachyoryctes splendens AFRICAN ROOT-RAT

Fr. Rat-taube de l'Est Africain; Ger. Afrikanische Maulwurfsratte (Afrikanischer Wurzelratte)

Tachyoryctes splendens (Rüppell, 1835). Neue Wirbelth. Fauna Abyssin. Gehörig., Säugeth. 1: 36. Gondar, Ethiopia.

Taxonomy Originally described in the genus *Bathyergus*. Here, *T. splendens* includes (as synonyms) 11 forms considered as valid species by Musser & Carleton (1993, 2005), i.e. *ankoliae*, *annectans*, *audax*, *daemon*, *ibeanus*, *naivashae*, *rex*, *ruandae*, *ruddi*, *spalacinus* and *storeyi*. Synonyms (of *T. splendens*; Musser & Carleton 1993, 2005): *canicaudus*, *cheesmani*, *gallarum*, *omensis*, *pontifex*, *somalicus*. Subspecies: none. Chromosome number: $2n = 48$ (Matthey 1956). See also profile Genus *Tachyoryctes*.

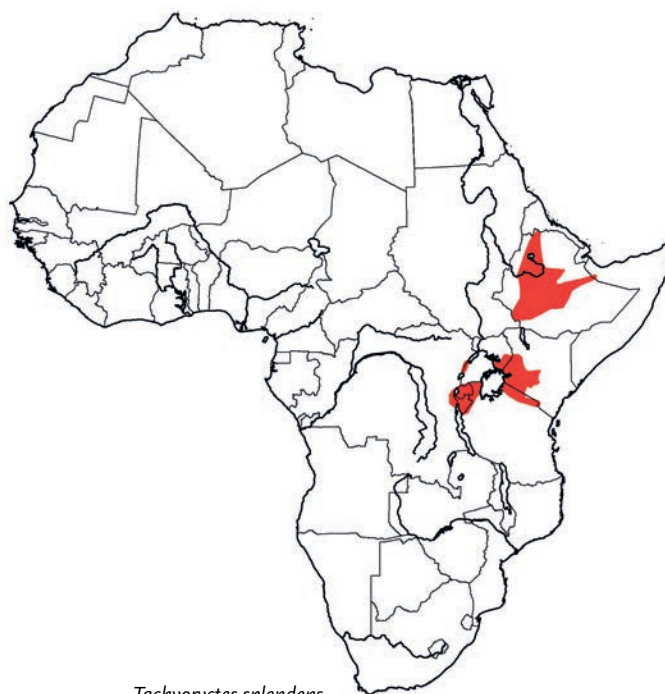

Description Very large subterranean rodent, solidly built with short limbs, and large orange incisors that are ungrooved, procumbent and extrabuccal. Pelage soft, thick and silky; hairs ca. 19 mm. Dorsal pelage ginger, cinnamon-brown or black (but variable) in adults, dark grey or black in juveniles. Ventral pelage paler, often tinged with buff. Patches of white pelage are common. Head similar in colour to dorsal pelage; lips have lateral folds. Well-developed vibrissae. Eyes small. Ears small, set close to head. Forelimbs short, with strong short claws; Digit 3 the longest digit; Digit 1 rudimentary. Hindfeet with five digits and short claws, Digit 2 the longest. Tail short (ca. 31% of HB), darkly pigmented above, well haired. Skull: rostrum thick, frontals constricted, occipital region prominent but not very high. Incisors large and wide (ca. 7 mm), pro-odont, and without grooves. Mandible with high recurved coronoid process and very prominent process between condylar and angular process (Figure 24). Males tend to be larger, weigh more and to be paler in colour than ♀♀. Nipples: $2 + 2 = 8$.

Geographic Variation Populations in different parts of the range differ in pelage colour, size and skull characteristics. This morphological variation can be explained by variations in soil characteristics (colour, hardness, structure) and the environment (rainfall, temperature, altitude, soil moisture). In any population, there is variation in (e.g.) pelage colour, shape of nasal bones, etc. (Ellerman 1940), which spans the variation of all described forms. Each of the 11 forms (listed as synonyms above) are allopatric and each occupies a very restricted distribution. (See also profile Genus *Tachyoryctes*.) The distribution of the various forms is as follows: *ankoliae*: SW Uganda; *annectans*: near lake Naivasha, Kenya; *audax*: Aberdare Range, Kenya; *daemon*: Mt Kilimanjaro, Mt Meru and district, N Tanzania; *ibeanus*: near Nairobi, Kenya; *naivashae*: L. Naivasha, Kenya; *rex*: Mt Kenya, Kenya; *ruandae*: mountains near L. Kivu (E DR Congo), Rwanda and Burundi, and possibly Rwenzori Mts, Uganda/E DR Congo; *ruddi*: Mt Elgon, Uganda/Kenya and Cherangani Hills, Kenya; *spalacinus*: between L. Naivasha and Mt Kenya, Kenya; *splendens*: most of Ethiopia and into NW Somalia; *storeyi*: L. Naivasha, Kenya.

Similar Species

T. macrocephalus. Much larger; Ethiopia only.

Heliophobius argenteocinereus. Similar size, white incisors (also extend beyond lips), no ear pinnae, very short tail.

*Tachyoryctes splendens*

Distribution Endemic to Africa. Afromontane–Afroalpine BZ and some adjacent areas. Recorded from highland areas in Ethiopia, NW Somalia, Kenya, Uganda, N Tanzania, Ruanda, Burundi and E DR Congo where annual rainfall is >510 mm. Occurs at altitudes above 1200 m, and reaches >4000 m in Kenya (Mt Kenya, Aberdare Ranges) and Tanzania (Mt Kilimanjaro).

Habitat Deep well-drained soils in savanna grasslands, open forests, afroalpine regions, agricultural fields and gardens.

Abundance Patchy and disjunct, but may be very common in suitable localities. Densities can be very high in cultivated land. Densities of 80 individuals/acre (= 200/ha) in a grassed area at Nairobi, Kenya (Jarvis 1973a), and of one individual/144 m² in E DR Congo (Rahm 1980) have been recorded. One field (100 m × 80 m) in E DR Congo contained 17 adult ♂♂, 16 adult ♀♀, nine juvenile ♂♂ and eight juvenile ♀♀ (Rahm 1980).

Adaptations Subterranean. African Root-rats live in a system of burrows 15–44 m long, comprised of foraging burrows 15–30 cm below ground, a slightly deeper nest chamber and a deeper bolt-hole ($n = 20$ burrow systems; Jarvis & Sale 1971, Rahm 1980). The nest chamber includes a sleeping area, a food store and a toilet area. The sleeping area, a hollow ball of grass and roots, lies close to the entrance of the nest chamber. The small food stores containing grass rhizomes, roots and geophytes are at the sides of the nest. The toilet area, behind the sleeping area, contains composting faeces and old nesting material, which generates heat. A rich invertebrate fauna, including

pseudoscorpions that feed on mites, is found in the nest chamber. African Root-rats dig by biting at the soil with their incisors. While digging, an animal will periodically turn round, and use one side of its head, and the foot of the same side, to hold the soil as it is pushed up a side branch leading to the surface. Once a mound has been completed, the side branch is thoroughly sealed. African Root-rats are diurnal, and active between 10:00h and 19:00h. Less than 25% of the 24-h day is spent out of the nest (Jarvis 1973b). They feel their way along the burrow by making small lateral movements of the head so the facial vibrissae brush the sides of the burrow. Unlike species of *Bathyergidae*, they rarely move backwards. They can rapidly turn around by curling on the side and walking round their almost stationary hindquarters.

Foraging and Food Herbivorous. The diet includes a wide variety of plants including grass rhizomes, stems and leaves, herbs, roots and storage organs of geophytes. African Root-rats may either dig up under a plant and pull the entire plant into the burrow, or forage around the periphery of an open hole. In this latter instance, they need to keep their eyes wide open and brace the hindfeet in the hole ready to effect a rapid retreat if alarmed. A foraging hole is plugged with a small and very characteristic heap of soil when foraging is complete (Jarvis & Sale 1971). Prior to eating small items of food, animals will grasp the food with the incisors and lightly brush the food with their cupped hands. Unless the item is very large, they walk forwards in the burrow while transporting food to the nest where it is eaten or stored. Stored bulbs and tubers are not disbudded when they sprout. African Root-rats do not drink water, obtaining their water requirements from their food.

Social and Reproductive Behaviour African Root-rats aggressively defend their burrow systems. They communicate seismically through the soil by tapping on the burrow floor with their upper incisors (Jarvis 1969a). Tapping consists of 3–10 taps, a pause and then a repeat of the sequence. Neighbouring animals will tap in response to each other's taps. When threatened, African Root-rats adopt an aggressive posture: the head is thrown back, jaws are agape and the feet are widely spaced and held stiff; the animal lunges forwards, snorting or squeaking and chattering its teeth. During aggressive encounters, or when alarmed, ♂♂ produce a strong musk-like odour from scent glands situated ventral to the eye and ear; ♀♀, in contrast, have very small glands. The position of the glands is clearly indicated by hairs that are stuck together by the secretions. The defensive posture is similar to the aggressive posture, but lacks vocalizations or tooth chattering. If completely submissive, an animal will lower its head and retreat (Jarvis 1969a).

Courtship is preceded by both animals tapping on the floor of their burrows. On meeting, ♂ emits a soft high-pitched twitter, the animals repeatedly lock incisors and ♀ will also squeak and gnash her teeth. Eventually ♀ turns, adopts the lordosis position, and ♂ mounts and bites her neck; during copulation, ♂ kneads flanks of ♀ with his hindfeet. Throughout copulation, which lasts 2–3 minutes, ♀ squeaks. Further copulations, which may continue at intervals for two days, are initiated by ♀. Between copulations, ♂ often rubs genital region on the floor, possibly marking the area with secretions from large bilobed preputial glands. The cellular structure of the two lobes is different: one produces a more oily secretion than the other and it is possible that they serve different functions. Unlike during the aggressive encounters, strong musk-odours are not produced during courtship (Jarvis 1969a).

Reproduction and Population Structure African Root-rats breed throughout the year, and are polyoestrous. Gestation: 46–49 days (Rahm 1969a). The ovary of pregnant ♀♀ contains accessory corpora lutea, and ♀♀ with full-term embryos have 2.5 corpora lutea per embryo. Foetal resorption occurs during pregnancy (Jarvis 1969b, Rahm 1980). Mating and a second pregnancy can occur during lactation. Litter-sizes are small: 1.65 (1–3) at Nairobi, 1.2 (1–3) at Nakuru, Kenya (Jarvis 1969b); 1.39 (1–4) at Kivu, E DR Congo (Rahm 1969a, 1980). At birth, young weigh 11–18 g (n = 14), are hairless and toothless. Fine hairs and small white incisors appear by Day 4. First solid foods eaten ca. Day 15–20. First leave nest Day 15–21. Eyes open Day 21–28. Digging and carrying food Day 24–30. Weaned ca. Day 35. Inter-sibling sparring begins at Day 37–60 and establishment of own burrow by Day 80. The vaginal closure membrane of young ♀♀ breaks down when 3 months old (Jarvis 1969a). Sex ratio at birth is parity (48.6%♂: 51.4% ♀, n = 3517), but biased towards ♀♀ in adults (58%, n = 9583) in E DR Congo (Rahm 1980). A similar bias towards ♀♀ occurred also in Kenya (Jarvis 1969a).

Predators, Parasites and Diseases Predators include Barn Owls (*Tyto alba*), diurnal birds of prey, small carnivores and snakes. These probably capture African Root-rats as they forage above ground in the vicinity of open holes. Ectoparasites include 15 species of fleas and 12 species of mites (Rahm 1980).

Conservation IUCN Category: Least Concern.

African Root-rats are considered agricultural pests in crops of cassava, sweet potato, peanuts, lucerne and maize. They also damage the roots of young trees and disfigure lawns and golf courses.

The family Nesomyidae encompasses several small groups of archaic muroid rodents whose living members are confined to sub-Saharan Africa (Cricetomyinae, Delanymyinae, Dendromurinae, Mystromyinae, Petromyscinae) and to Madagascar (Nesomyinae). In Africa, the family is represented by five subfamilies, 12 genera and 34 species. Each of the subfamilies is morphologically well characterized, but the family itself lacks clear diagnostic features in view of the immense heterogeneity embraced. Collectively, the five African subfamilies are highly diverse in size and morphology, habits, trophic niche and ecology (see subfamily and genus profiles).

Tullberg (1899) and later Chaline *et al.* (1977) recognized the Nesomyidae, but the content of the family was largely restricted to the indigenous Malagasy rodents as previously identified by Major (1897) at the rank of subfamily. Although differing in contents, the family composition observed here owes its conceptual roots to Lavocat (1973, 1978), who identified a number of small but morphologically well defined groups as relicts of a middle Tertiary (late Oligocene–Miocene) cricetodontine presence in Africa and

broadened the definition of Nesomyidae to embrace their diverse descendants (also see Carleton & Musser 1984). Prior to Lavocat's contributions, these archaic African muroids had been variously and inconsistently divided between Cricetidae and Muridae, or all were placed in an inclusive Muridae (see Carleton & Musser 1984, for classificatory review).

The family's expanded composition was initially based on tenuous dental links to middle Tertiary fossils, but results of molecular phylogenetic studies, although not wholly concordant, supply additional empirical support for Lavocat's view of Nesomyidae. These gene-sequence investigations associate Cricetomyinae, Dendromurinae, Mystromyinae and Nesomyinae as a monophyletic lineage (Nesomyidae) basal to other muroid taxa that represent Cricetidae and Muridae (DuBois *et al.* 1996, Jansa *et al.* 1999, Michaux & Catzeflis 2000, Michaux *et al.* 2001). Tong & Jaeger (1993), on the other hand, considered Lavocat's family to be a polyphyletic wastebasket that encompasses the remnants of early evolutionary branches leading to the major radiations of Cricetidae or Muridae. The evidence needed to settle these issues of relationship and classification will require greater emphasis on molecular and genetic characters and more extensive studies on morphology (rather than on dentition).

The antiquity of the five African subfamilies is substantiated by palaeontological information. Evolutionary origin of each has been linked, with varying degrees of confidence, to early Miocene to early Pliocene fossil genera, most of these known from sub-Saharan sites (see subfamily accounts). Only the Dendromurinae is firmly documented outside of sub-Saharan Africa in the middle Tertiary (e.g. Aguilar *et al.* 1984, De Bruijn 1999). The palaeontological argument for such phyletic connections remains sketchy and the hard evidence from critical middle Tertiary beds is scanty. Further discoveries from the Tertiary of Africa will help to clarify the validity of the family.

Compared with the African radiations of Gerbillinae and Murinae (Muridae), each of the subfamilies of Nesomyidae contains few genera and species: Cricetomyinae (3 genera, 5 species); Delanymyinae (1 genus, 1 species); Dendromurinae (6 genera, 23 species); Mystromyinae (1 genus, 1 species); and Petromyscinae (1 genus, 4 species).

Michael D. Carleton & Guy G. Musser

Subfamily CRICETOMYINAE – Pouched Rats and Pouched Mice

Cricetomyinae Roberts, 1951. Mammals South Africa, p. 434.

The three genera and five species comprising this subfamily are endemic to Africa, occurring in sub-Saharan savannas and in lowland and montane rainforest. Only one genus is found in West Africa (*Cricetomys*), but all three genera are represented in eastern and southern Africa (*Beamys*, *Cricetomys* and *Saccostomus*). Species in the

three genera are terrestrial and nocturnal, or predominantly so, consume seeds, fruits and bulbs, build relatively complex burrow systems, and hoard foods within those burrows for immediate or later consumption. The last habit is due, in part, to the possession of internal cheek pouches (a cardinal morphological trait of the

subfamily), which are used to carry food from the foraging area to the burrow. Capacious cheek pouches have also evolved within other lineages of Rodentia, namely Sciuridae (squirrels) and Geomyoidea (pocket gophers, kangaroo mice and rats), but in muroid rodents, such pouches characterize only this subfamily and the Palearctic hamsters (Cricetidae: Cricetini). Details of buccal histology, myology and innervation indicate that pouches were independently acquired by these muroid subfamilies (Ryan 1989). The infrequency of elastin fibres and absence of distensible folds in the pouch walls of cricetomyines suggest that they do not hoard foodstuffs or accumulate the vast underground larders to the extent documented for the cricetine hamsters.

Species in the subfamily are small (*Saccostomus*) to very large (*Cricetomys*) in size. They have a robust body, large head, comparatively short and stout limbs and very short (*Saccostomus*) or very long (*Beamys*, *Cricetomys*) tail. The cheek pouch retractor is derived from facial muscle, innervated by cranial nerve VII and originating from the anterior thoracic vertebrae (Ryan 1989). Hindfeet strongly built, broad across the metatarsus, with short toes that have inconspicuous ungual tufts; plantar surface naked with six pads, the thenar and hypothernar positioned distally and close to four interdigitals. The skull characters include strong construction, rostrum moderately long and interorbital region hourglass-shaped with edges squared to slightly beaded; zygomatic plate with slight dorsal notch, jugal forming a prominent element of the middle zygomatic arch; alisphenoid strut present; subsquamosal fenestra absent, postglenoid foramen present; tegmen tympani not overlapping squamosal (Carleton & Musser 1984). Molars cuspidate, uppers with three roots and lowers two; upper molars with accessory lingual conules positioned to form transverse laminae suggestive of a rudimentary triserial arrangement, lowers with labial conulids; longitudinal enamel connections between lamina absent (Petter 1966a, c). Upper incisors without grooves, lowers with inconspicuous parallel enamel striae (Pocock 1987). The cephalic arterial circulation lacks a supraorbital branch of stapedial artery (sphenofrontal foramen and squamosal-alisphenoid groove are absent), but the infraorbital branch is present (stapedial foramen and parapterygoid groove are present).

For so distinctive and closely related a group, African Pouched Rats and Mice were not formally acknowledged taxonomically until Roberts's (1951) classification of South African mammals. In the early systematic literature, the three genera were classified within

Murinae (e.g. Thomas 1897, Ellerman 1941, Simpson 1945), but subsequent systematic arrangements have followed Petter (1966a, c) in allying cricetomyines with cricetids (e.g. Misonne 1974, Rosevear 1969, Skinner & Smithers 1990). Molar occlusal configuration (Petter 1966a) and anatomy of internal cheek pouches (Ryan 1989) convincingly sustain the monophyly of the subfamily. Mitochondrial and nuclear DNA sequence data (Jansa *et al.* 1999, Michaux & Catzeflis 2000, Michaux *et al.* 2001) also support monophyly and indicate that Cricetomyinae is phylogenetically close to Dendromurinae and Mystromyinae, two other endemic African subfamilies. Indisputable fossil representatives are known from the late Miocene to Recent of eastern and southern Africa (Denys 1988, Senut *et al.* 1992, Avery 1995, 1996, Mein *et al.* 2004), and the autochthonous African origin of Cricetomyinae has been speculatively linked to Miocene Afrocricetodontinae, a phyletic connection that so far lacks persuasive demonstration (Chaline *et al.* 1977, Tong & Jaeger 1993).

Roberts (1951) segregated *Saccostomus*, as a lone member of Saccostomurinae, from other African pouched rats (Cricetomyinae), a division not recognized by later systematists (Petter 1966a, Ryan 1989); however, morphological traits and gene-sequence data link *Beamys* and *Cricetomys* as cognate relatives separate from *Saccostomus* (Carleton & Musser 1984, Corti *et al.* 2004).

Two tribes within the subfamily may be recognized: (1) Cricetomyini (*Beamys*, *Cricetomys*): tail longer than combined head and body; anterior palatal foramina short; bony palate relatively short, lacking posterolateral palatal pits; mesopterygoid fossa moderately long; alisphenoid bone possessing dorsal orbital flange; accessory foramen ovale present; ectotympanic bullae (part of auditory bullae) small; vertebral column with 13 thoracic and six lumbar vertebrae; entepicondylar foramen of humerus present; corpus of stomach densely papillated; (2) Saccostomurini (*Saccostomus*): tail conspicuously shorter than head and body; anterior palatal foramina long; bony palate long with prominent posterolateral palatal pits; mesopterygoid fossa short and wide; alisphenoid lacking dorsal flange; accessory foramen ovale absent; ectotympanic bullae moderately inflated; vertebral column with 12 thoracic and seven lumbar vertebrae; entepicondylar foramen absent; corpus smooth, lacking papillae.

The three genera and five species are listed alphabetically below.

Michael D. Carleton & Guy G. Musser

GENUS *Beamys*

Long-tailed Pouched Rat

Beamys Thomas, 1909. Ann. Mag. Nat. Hist., ser. 8, 4: 107. Type species: *Beamys hindei* Thomas, 1909.

The genus *Beamys* contains of one (or two) species confined to evergreen forests of eastern Africa. *Beamys* is probably close to the ancestral stock of the Cricetomyinae. Two of its features, its habitat and the presence of an ectoparasite *Hemimerus*, which also occurs on *Cricetomys*, are considered to be primitive characters. Many of the characters of *Beamys* such as cheek pouches, body shape, shape and colouration of tail, reduction of M³ and only two cusps on the lamina of M¹ are similar to those of *Cricetomys* (Hanney & Morris 1962,

Petter 1966c) (Figure 25). Musser & Carleton (2005) regard the two taxa, *hindei* and *major*, as separate species. An alternative arrangement is that there is a single species that shows a geographic cline in size – the smaller *hindei* in the northern part of range and the larger *major* in the southern part of range. Here, the genus is considered to have single species *Beamys hindei*. See also profile *Beamys hindei* below.

D. C. D. Happold

***Beamys hindei* LONG-TAILED POUCHED RAT**

Fr. Petit rat à abajoues; Ger. Langschwanz-Hamsterratte

Beamys hindei Thomas, 1909. Ann. Mag. Nat. Hist., ser. 8, 4: 108. Taveta, Coastal Province, Kenya.

Beamys hindei.

Taxonomy *Beamys hindei* was described in 1909 from an immature individual with a small hindfoot collected in S Kenya. Subsequently the species was shown to occur throughout E Tanzania. A second species (*B. major*), with a larger hindfoot, was described in 1914 from Malawi and is now known to occur also in E Zambia. Some authors (e.g. Misonne 1974, Musser & Carleton 1993, 2005) retain these two species, but others (e.g. Ansell & Ansell 1973, Fitzgibbon *et al.* 1995) consider *major* as a subspecies of *hindei*. Fitzgibbon *et al.* (1995) show that there is a trend for individuals from southerly latitudes to be slightly larger than those from northerly latitudes. Specimens of *major* from Malawi are only slightly larger than those from S Tanzania, as would be expected from the general trend of increasing size from north to south. Here, all populations from Kenya to Malawi are considered as belonging to a single species, *B. hindei*, which shows clinal variation in size; northern populations are referred to as *B. h. hindei* and southern populations as *B. h. major*. Synonyms: *major*. Subspecies: two. See also profile genus *Beamys*. Chromosome number: $2n = 52$ (Fitzgibbon *et al.* 1995).

Description Medium-sized rat, soft grey dorsally, white ventrally, and with thick whitish blotched tail. Dorsal pelage warm grey, sometimes with a russet tinge on rump and back; dorsal hairs medium grey with warm grey tips. Ventral pelage, chin, throat pure white. Pelage dense and soft. Face pointed, ears small and rounded; vibrissae long and black; eyes black, small. Some individuals have white blaze on forehead. Limbs short, fore- and hindfeet white. Forefeet with four digits; hindfeet five digits. Tail long (ca. 100% of HB), scaly, thick (especially at base), whitish often with irregular dark blotches. Dorsal pelage of juveniles pale grey. For most measurements, ♂♂ are larger on average than ♀♀.

Geographic Variation

B. h. hindei: northern part of range. On average, smaller in size.

B. h. major: southern part of range. On average, larger in size.

Figure 25. Skull and mandible of *Beamys hindei* (HC 2787).

Similar Species

Cricetomys gambianus. Much larger and heavier (mean HB: 326 mm); relatively long tail (ca. 85–130% [mean 107%] of HB); terrestrial, wider distribution.

Saccostomus campestris. Smaller (mean HB: ca. 114 mm), broader head; relatively short tail (ca. 44–50% of HB); terrestrial, wider distribution, not confined to forested habitats.

Distribution Endemic to Africa, Zambezan Woodland BZ and Coastal Forest Mosaic BZ. Recorded from coastal forests within about 100 km of coast from S Kenya to S Tanzania (*B. h. hindei*), and extreme SW Tanzania, Malawi (and perhaps parts of N Mozambique) and NE Zambia (*B. h. major*). Investigations in suitable habitats between the ranges of the two subspecies have failed to find any individuals (Fitzgibbon *et al.* 1995).

Habitat Evergreen or slightly deciduous forests preferably on sandy soils, and gallery forests associated with streams. At Arabuko-Sokoke, SE Kenya, these Pouched Rats also occur in *Afzelia* forest and, to a lesser extent, *Brachystegia* forest. Occasionally found on fallow land and cassava plantations (Kenya only).

Abundance Sparsely distributed; recorded from only a few localities but commoner than previously realized. In most localities, only one or two individuals have been found (perhaps because of trap-shyness). In a few optimal habitats, populations may be high, e.g. at Arabuko-Sokoke, where trees were close together and there

was dense vegetation below 4 m, density was 14–30 individuals/ha. Comparable abundance is known in at least one mixed dry forest in the northern East Usambara lowlands, but the species was surprisingly scarce 700 m higher in sub-montane habitats (N. Cordiero unpubl.).

Adaptations Nocturnal, scansorial. Although mainly terrestrial, can clamber about on twigs and small branches. When climbing, the tip of the prehensile tail is twisted around a twig, or it is held straight backwards as a counterbalance. During the day, individuals rest in a burrow. Most burrows have a straight vertical shaft with a nest chamber and latrine chamber. The nest is lined with fresh green leaves, which are changed regularly.

When foraging, seeds and other foods are collected and stored in the cheek pouches. The food is taken to the nest and disgorged. Pouched Rats store considerable quantities of food, which is eaten when conditions for foraging are poor (see below).

Pouched Rats are slow-moving and lethargic, spending a lot of time curled up in their nests. During cool weather, they may become dormant.

Foraging and Food Forage on the ground and in trees. Omnivorous, feeding primarily on seeds and fruits, and occasionally insects. Food is stored in the nest. One excavated nest (*B. h. major*) contained nearly 1400 seeds of several species (weight ca. 1200 g), which would have taken about 200 separate forays to collect (Hanney & Morris 1962).

Social and Reproductive Behaviour Usually solitary. In captivity, ♀♀ not in breeding condition attack ♂♂, biting them on hips, tail and scrotum. Receptive ♀♀ have been observed to perform a 'forwards and backwards' dance in a circular area in front of ♂, as well as biting him, prior to copulation (Hubbard 1970a).

Reproduction and Population Structure Times of reproduction depend on the locality. At Arabuko-Sokoke, reproduction occurs in most months of the year (Fitzgibbon *et al.* 1995). Lactating ♀♀ were present for nine months of the year (but not in Nov, Mar and Aug, the months of lowest rainfall); ♂♂ had scrotal testes in all months. However, only a proportion of all individuals were reproductively active in any month: 20–60% of ♀♀ were lactating during the nine months, and 50–90% of the ♂♂ were scrotal (except Sep – 25%). The highest percentage of breeding ♀♀ was in May at the height of the wet season. Females bred at least once per year. In Malawi, reproduction is seasonally polyoestrous; pregnant ♀♀ have been recorded Nov–May during the wet season and the beginning of the dry season (Hanney & Morris 1962); during the (cold and hot) dry season (Jun–Nov), testes of ♂♂ were abdominal.

Studies on captive animals (*B. h. hindei*) have provided detailed information on reproduction (Egoscue 1972): age at first conception: ca. 7–9 months. Gestation 22–23 days. Eyes of young open Day 21. Weaning Day 35–40. Minimum interval between births 62 days; no postpartum oestrus. Litter-size: 2.8 (1–5, mode 3, n = 39). In Malawi, litter-size: 4.6 ([n = 4] and 7 [n = 1]). Young born with pink-coloured skin and a fine down of grey hairs; wt 3.2 (2.1–4.3) g. Growth is rapid; at four weeks young are still suckling and weigh ca. 43 g (Hanney & Morris 1962). Longevity in captivity: 3–4 years.

At Arabuko-Sokoke, where breeding occurred throughout most of the year, there was a low but continuous recruitment of young individuals into the population. Numbers remained fairly constant throughout the year (14–30/ha) but with a peak in May and Jun due to recruitment of many young. There appears to be no seasonal change in weight.

Predators, Parasites and Diseases Remains of Pouched Rats have been found in owl pellets at Lunzu, Malawi (Hanney 1962), and one individual was found in the stomach of a Twig Snake (*Thelatornis capensis*) at Namakutwa, Tanzania (Fitzgibbon *et al.* 1995). In Malawi, nests of Pouched Rats may be infested with ectoparasitic earwigs (*Araeomerus morrissi*, formerly *Hemimerus morrissi* [Nakata & Maa 1974]) where it is assumed they feed on stored fruits, and less frequently on the skin of Pouched Rats (Popham 1984). One species of flea, *Xenopsylla microphthalmia*, has been recorded (Beaucornu & Kock 1996). (See also Genus *Cricetomys*.)

Conservation IUCN Category: Least Concern.

Populations are small and widely dispersed, and their forest habitats are being modified or reduced in area by human activities. (IUCN previously recognized *hindei* and *major* as full species; both were considered as Near Threatened.) Populations numbers are considered to be declining.

Measurements

Beamys hindei

HB (♂♂): 146 (135–158) mm, n = 5

GENUS *Cricetomys* Giant Pouched Rats

Cricetomys Waterhouse, 1840. Proc. Zool. Soc. Lond. 1840: 2. Type species: *Cricetomys gambianus* Waterhouse, 1840.

Cricetomys gambianus.

The genus contains two to four species, and is distributed extensively throughout sub-Saharan Africa to about 27°S, including Zanzibar and Bioko Islands. The genus is represented in nearly all habitats from dry savanna to rainforest, and is often associated with human settlements.

Giant Pouched Rats are distinguished from most other African murids by their very large size, unscaled and bi-coloured tails (basal half dark, terminal half white), and ungrooved incisors (Figure 26). They have internally opening cheek pouches, a character shared with the other two genera in the subfamily Cricetomyinae (*Beamys* and *Saccostomus*).

The number of species in the genus is uncertain. Allen (1939) recognized six species, and Ellerman (1941) reduced these to subspecies of a single species, *C. gambianus*. Genest-Villard's (1967) revision provided evidence of two 'species', a predominantly savanna-dwelling species (*C. gambianus*) and a rainforest species (*C. emini*) (see Musser & Carleton 1993). These two species are recognized here. Musser & Carleton (2005) accept these two species for West Africa, but claim that Genest-Villard's character states and univariate analysis do not discriminate the southern African forms of the genus. These authors name the southern African forms of the genus as *C. ansorgei* and *C. kivuensis*. *Cricetomys ansorgei* (given as synonym of *C. gambianus* by Musser & Carleton 1993) is the savanna-living form, occurring in East Africa (including Zanzibar), westwards to Angola and southwards to South Africa. *Cricetomys kivuensis* (given as

Figure 26. Skull and mandible of *Cricetomys gambianus* (HC no number).

synonym of *C. emini* by Musser & Carleton 1993) is a forest-living form, known from montane habitats of E DR Congo, S Uganda, Rwanda and Burundi.

The two species recognized here are: *Cricetomys emini*, which has soft, sleek dark brown pelage, a pointed face and is restricted to the Rainforest BZ; and *Cricetomys gambianus*, which has rather coarse greyish-brown pelage, a wide blunt face, and is restricted to savanna habitats and 'savanna-like' habitats around the margins of the Rainforest BZ.

Justina C. Ray & J.-M. Duplantier

***Cricetomys emini* EMIN'S GIANT POUCHED RAT (FOREST GIANT POUCHED RAT)**

Fr. Rat Géant d'Emin; Ger. Emins Riesenhamsterratte

Cricetomys emini Wroughton, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 269. Monbuttu, Gadda, DR Congo.

Taxonomy Synonyms: *dissimilis*, *dolichops*, *kivuensis*, *liberiae*, *luteus*, *poensis*, *proparator*, *sanctus*, *tephrus*. The form *kivuensis* is regarded as a valid species by Musser & Carleton (2005; see profile Genus *Cricetomys*). Grubb (2004) suggests that the correct specific name for this species may be *C. dissimilis* de Rochebrune, 1885 (see also Hatt 1940). Subspecies: none. Chromosome number: $2n = 80$, $aFN = 80$ (Codjia *et al.* 1994).

Description Largest of the African forest murid rodents; similar to *C. gambianus* but with slender body form. Pelage short, sleek and soft in texture. Dorsal pelage orange-brown to dark greyish-brown or brownish-black. Head and flanks generally paler in colour. Ventral pelage white; usually well delineated from colour of flanks. Guard hairs few in number but very long. Face narrow in appearance with large, pale, naked ears standing well above pelage. Whiskers numerous and long. Dark eye-ring absent. Limbs long and thin. Feet whitish, long and powerful, but with relatively short claws. Digit 5 of the forefoot rudimentary; Digit 5 of hindfoot reaches to about half the length of Digit 4. Tail very long (ca. 115% of HB), smooth without scales, dark on basal half, white on terminal half. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

C. gambianus. More thick-set in body form, pelage rough, shaggy and longer; ventral pelage off-white, not clearly delineated from flanks; face broader with dark eye-ring; ear smaller, partly submerged in pelage; occurs in grasslands, woodlands and anthropogenic habitats in savannas, but sympatric with *C. emini* in some localities along edge of Rainforest BZ.

Distribution Endemic to Africa. Widespread in Rainforest BZ and Rainforest–Savanna Mosaics. Recorded from Sierra Leone to S Uganda, Rwanda, Burundi, DR Congo, NE Angola, Equatorial Guinea, Gabon and Congo, Bioko I. (Fa 2000).

Habitat Prefers 'high forest' as opposed to open savanna or commensal habitats (Rosevear 1969; Genest-Villard 1967). Within rainforest, demonstrates no marked preference for habitat type (Ray 1996). Also occurs in secondary forest along logging roads (Ray 1996, Malcolm & Ray 2000). In Dzanga-Sangha, Central African Republic, Forest Giant Rats were captured most often where the understorey was relatively open (Ray 1996).

Abundance Mean population density at three sites in central Africa is $134.0 \pm 16.9/\text{km}^2$ (Fa & Purvis 1997). Probably much more abundant than assessed by trapping (Dosso 1975b). Although only ten individuals were captured during 23,291 trap-nights in Taï Forest, Côte d'Ivoire, these Giant Rats were the species most often purchased from villagers or collected during night surveys on forest trails (Dosso 1975b).

*Cricetomys emini*

Adaptations Generally terrestrial, but able to climb and jump (Kingdon 1974). Captured frequently at height of 2 m in Dzanga-Sangha, Central African Republic, but significantly more abundant on the ground (Malcolm & Ray 2000). Nocturnal (Rahm 1967), but occasionally seen in daylight (Rosevear 1969). Shelters in underground burrows, either modified or self-constructed, among large tree roots, and in holes in rotten logs and fallen tree trunks (J. C. Ray unpubl., Sanderson 1940). Burrows are characterized by a 'complex system' of galleries with side branches and separate chambers for food storage, sleeping, or waste; there are several escape routes. Nests are lined with fresh leaves. Individuals constantly change burrows (Rosevear 1969). Well worn pathways are used regularly for travelling within the home-range (J. C. Ray unpubl., Sanderson 1940).

Foraging and Food Mainly vegetarian. Consumes wild and cultivated fruits (Rahm & Christiaensen 1963, Rosevear 1969). Snails also an important food-source (Rahm & Christiaensen 1963). Termites discovered in one stomach (Hatt 1940a). Detailed analysis of diet not available. Coprophagous.

Social and Reproductive Behaviour Solitary except when raising young. One individual to a burrow (Rosevear 1969). Produces call that is modulatory in nature, the function of which is unknown (Genest-Villard 1967).

Reproduction and Population Structure Lives up to 4.5 years in captivity. Gestation 42 days. Litter-size: 2–4 (Rosevear 1969).

Predators, Parasites and Diseases Humans are the most important predators. These Giant Rats are particularly common in local food markets throughout central and West Africa in those areas where ungulates and primates are rare (Fa 2000). Ranked the second commonest species at bushmeat markets on Bioko I., and eighth commonest species at markets in Rio Muni (Equatorial Guinea). Daily availability ranged from 0.43 carcasses (Rio Muni) to 5.3 (Bioko I.; Juste *et al.* 1995). Most common rodent in markets in Kisangani, DR Congo, representing 90% of 35,992 rodent carcasses (Colyn *et al.* 1987).

Remains are commonly found in the scats of mammalian carnivores, such as mongooses *Herpestes naso* and *Bdeogale nigripes*, genets *Genetta servalina*, African Civets *Civettictis civetta* and Golden Cats *Profelis aurata*, at a frequency of occurrence ranging from 3.3 to 11.8% (Ray & Sunquist 2001). Found in 4.9% (n = 150) of scats of Leopards *Panthera pardus* from Dzanga-Sangha, but in only 1.9% (n = 215) of scats from Taï Forest, Côte d'Ivoire (Hoppe-Dominik 1984). Absent in leopard scats (n = 222) from Ituri Forest, DR Congo, where leopards prey on larger species (Hart *et al.* 1996).

As for *C. gambianus*, ectoparasites include *Hemimerus* spp. The nematode *Capillaria hepatica* parasitizes the liver, and is known to have zoonotic potential, causing human hepatic capillariasis. A relatively high prevalence (27%) of this nematode has been recorded in wild-caught *C. emini* in DR Congo; because Giant Rats are frequently consumed by humans, this level of parasitism has important implications for public health (Malekani 1994).

Conservation IUCN Category: Least Concern.

Potential threats are overhunting close to human population centres where primates and ungulates have been depleted, and

where there has been deforestation. A well-known pest in cocoa farms where these rats climb the trunks of cocoa trees to feed on cocoa pods. In Sierra Leone, *C. emini* may be displaced by *C. gambianus* following removal of rainforest habitats (Grubb *et al.* 1998).

Measurements

Cricetomys emini

Cricetomys gambianus GAMBIAN GIANT POUCHED RAT

Fr. Rat Géant de Gambie; Ger. Gambia-Riesenhamsterratte

Cricetomys gambianus Waterhouse, 1840. Proc. Zool. Soc. Lond., 1840: 2. River Gambia, Gambia.

Taxonomy Considered to include *C. emini* until the revision of Genest-Villard (1967) who clearly separated the two species and distinguished seven subspecies (currently synonyms) of *C. gambianus*. Synonyms: *adventor*, *ansorgei*, *buchanani*, *cosensi*, *cunctator*, *dichrurus*, *dissimilis*, *elgonis*, *enguvi*, *gambiensis* (spelling *lapsus*), *goliath*, *grahami*, *haageni*, *langi*, *microtis*, *oliviae*, *osgoodi*, *selindensis*, *servorum*, *vaughanjonessi*, *viator*. The form *ansorgei* is considered as a valid species by Musser & Carleton (2005; see profile Genus *Cricetomys*). Subspecies: none. Chromosome number: 2n = 78 (unknown origin, Matthey 1954), 2n = 80, aFN = 82 (Senegal; Granjon *et al.* 1992) and 2n = 82, aFN = 88 (Benin; Codjia *et al.* 1994).

Description The largest murid species in Africa (together with *C. emini*). Dorsal pelage coarse, rough and shaggy, ranging in colour from grey (savannas of West and central Africa to Uganda) to brown in the eastern and southern parts of the range. Flanks paler. Ventral pelage white to off-white, not clearly delineated from colour of flanks. Face broad with elongated muzzle; very long vibrissae. Eyes relatively small with dark eye-ring. Ears relatively large, lower part usually submerged in pelage. Limbs relatively short compared to

body size. Forefoot with a rudimentary thumb; hindfoot strong but with rather small claws. Tail long (85–130% [mean 107%] of HB), dark blackish-brown on proximal half, white on terminal half; smooth without scales and with short and sparse hairs on proximal end. Length of white tip varies regionally (31–68% [mean 50%] in Senegal [J.-M. Duplantier unpubl.]; 37–46% [mean 41%] for ♂ ♂, 31–45% [mean 38%] for ♀ ♀ on NTransvaal, South Africa [Smithers 1983]). Nipples: 2 + 2 = 8.

Geographic Variation Genest-Villard (1967) recorded seven subspecies (not recognized here):

C. gambianus: West and central Africa. Dorsal pelage predominantly grey; proximal part of tail very dark.

C. ansorgei: south of the Rainforest BZ. Dorsal pelage predominantly brown, more yellowish than *C. g. gambianus*; longer body length than *C. g. gambianus*. (Musser & Carleton [2005] recognize this form as a valid species, and give the five forms listed below as synonyms of *C. ansorgei*.)

C. microtis: Virunga Mts, DR Congo. The darkest and smallest form.

C. elgonis: Mt Elgon, Uganda/Kenya. Dark thick dorsal pelage and longer body length.

C. kenyensis: Mt Kenya; skull narrow.

C. enguvi: Taita hills and base of Mt Kilimanjaro (Kenya). Skull narrow and longer body length.

C. cosensi: Zanzibar. Very large anterior palatal foramina; narrowest skull and the longest body length.

Similar Species

C. emini. Slender body form; pelage shorter and softer, ventral pelage white, clearly delineated from flanks; face narrow without dark eye-ring; ears larger and standing above pelage, skull more elongated (Genest-Villard 1967); restricted to rainforest habitats.

Distribution Endemic to Africa. Widespread in Sudan and Guinea Savanna BZs, Zambezian Savanna BZ, Rainforest–Savanna Mosaics and marginally in southern part of Somalia–Masai BZ. Occasionally in Sahel Savanna BZ (see below). North of the Congo Basin recorded from Senegal and Guinea to Sudan, Uganda and Kenya; south of the Congo Basin recorded from Angola, S DR Congo, Zambia, Malawi, Tanzania, Mozambique and South Africa (KwaZulu–Natal and former Northern Transvaal Provinces) (Genest-Villard 1967, Smithers 1983). The distribution of *C. g. ansorgei* (see above) includes SE Kenya, Tanzania and all of the area from Angola to Mozambique and N South Africa. Zanzibar I.

Habitat Widespread in savanna habitats. Also recorded in human-modified habitats on edge of Rainforest BZ (Rosevear 1969, Happold 1987). In the Sahel Savanna BZ, found only in large cities. In the south-eastern part of its range, restricted to evergreen forests and moister habitats (Morris 1963, Skinner & Smithers 1990). Often commensal.

Abundance Generally considered as abundant throughout the range, but few quantitative data. Forty-five burrows found on a 5 ha

farmland in Nigeria (Ajayi 1975), 42 individuals taken from 0.5 ha garden in Zimbabwe (Smithers 1983).

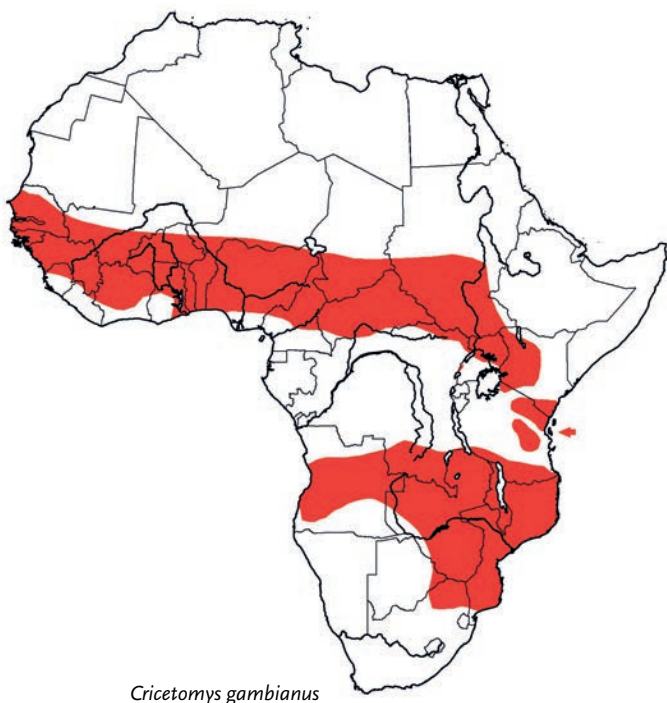

Adaptations Typically terrestrial, and predominantly nocturnal (Morris 1963, Ewer 1967). Giant Rats walk and run on all four legs, usually with the tail raised; they are good climbers and jumpers (Happold 1987). Nocturnal activity shows two peaks of activity, one at the beginning and one at the end of the night (Knight 1984). Burrows are often located in termite mounds or within the root system of large or dead trees (Morris 1963, Ajayi 1977), and range from 0.9 m to 2.9 m in length, with 50% less than 1.8 m (Ajayi 1977). A typical burrow has a large entrance leading to a nesting chamber composed of a nest, food store and sanitary area, and smaller additional burrows leading to small exit (escape) holes (Ajayi 1977). Burrows are excavated using the incisor teeth rather than claws (Morris 1963). May also live in rainwater drains and under houses.

Tooth-gnashing, inflation of cheek pouches (thus making the head appear larger than normal) and a 'puffing sound' are produced when threatened. Vocalizations for intra-specific communication include 'loud squeaks', 'high squeaks' and 'piping squeaks' (Ewer 1967).

Foraging and Food Omnivorous, but mainly vegetarian. The large cheek pouches are used to transport food (and nesting materials) to food stores in the nest (Ewer 1967). Food is frequently hoarded in nests: in Transvaal, South Africa, 8.7 kg of macadamia nuts were found in a single burrow (Knight 1984) and in Nigeria, 50% of stored food was palm fruits (Ajayi 1977). Diet of ♂♂ in S Nigeria (from stomach analysis, $n = 5$) was palm fruits (72%), seeds (12%), insects (7%) with some quantities of other fruits. Females consumed fewer palm fruits, but larger amounts of other fruits and vegetables. Diet varies according to location and food availability, and may include small quantities of animal matter (Iwuala *et al.* 1980). Most diets include adequate moisture but free water is drunk when necessary. Coprophagy appears to be a common habit (Ewer 1967).

Social and Reproductive Behaviour Generally considered to be solitary in the wild, but Happold (1987) mentions the presence of several individuals in the same burrow. In captivity, ♂♂ and ♀♀ can be kept together easily (Ewer 1967). Litter-mates may show aggressive behaviour toward each others (Ewer 1967). Home-ranges are 2.2–11 ha (mean ca. 5 ha; Skinner & Smithers 1990); home-ranges of ♂♂ larger than those of ♀♀. Detailed descriptions of complex courtship and mating behaviour, as well as parental–young interactions, in captivity are given by Ewer (1967).

Reproduction and Population Structure Pregnant ♀♀ and adults in breeding condition found all year round in Nigeria (Anizoba 1982). Young recorded between Sep and May in Malawi, suggesting that breeding takes place during the wet season (Morris 1963). Gestation: 27–42 days (Morris 1963, Ewer 1967, Ajayi 1975). Litter-size: 3 (1–5). Average weight at birth: 16–27 g, depending on litter-size; altricial; eyes closed, hairless. Silky covering of hair Day 10. First walking Day 16. First eating of solid food Day 18. Eyes open Day 20–24. Collects food in cheek pouches ca. Day 25, coprophagy Day 25 (Ewer 1967). Sexual maturity about 20 weeks for both sexes (Ajayi 1975).

Cricetomys gambianus

Predators, Parasites and Diseases Predators include the Steppe Eagle *Aquila rapax* and eagle-owls *Bubo capensis* and *Bubo lacteus* (De Graaff 1981). Highly appreciated by humans as bushmeat. In W Nigeria, ranked as the 2nd (22%) or 4th (8%) commonest species for sale as bushmeat (Martin 1983, Anadu *et al.* 1988) after small antelopes, Cane Rats and Brush-tailed Porcupines (Martin 1983). Ranked 20th of preferred wild animals as a source of food in N Cameroon (Njiforti 1996). Eaten frequently in East Usambara Mts as well as in other coastal and montane forests in E Tanzania (N. Cordeiro unpubl.).

Several species of *Hemimerus* ectoparasites (Insecta: Dermoptera; earwig family) are specific to *Cricetomys gambianus*, including *H. talpoides*, *H. prolixus*, *H. deceptor*, *H. bouvieri* (Ashford 1970, Popham 1984). *Hemimerus* is the only known parasitic member of this insect family (Happold 1987) and is found only on species of *Cricetomys* and *Beamys*. Other ectoparasites include a variety of ticks, mites and fleas; major intestinal parasites are tapeworms. Among human pathogens, *Babesia* and *Bartonella* bacteria have been identified in the blood (Dipeolu & Ajayi 1976); in West Africa, several viruses (including Bandia, Uganda S, Dugbe and Gabek-Forest) have been isolated from body organs of *C. gambianus* (Saluzzo *et al.* 1986).

Conservation IUCN Category: Least Concern.

Common and widespread species, and not threatened. Bred in captivity as a supply of 'bushmeat' (Ajayi 1975).

GENUS *Saccostomus*

Pouched Mice

Saccostomus Peters, 1846. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin, 11: 258. Type species: *Saccostomus campestris* Peters, 1846.

Saccostomus campestris.

The genus comprises two species widely distributed in savanna habitats in East and South Africa. Species in the genus are small-medium in size (and smaller than other members of the family), solidly built with broad heads, short limbs and short tails. Cheek pouches are well developed. The skull is characterized by long anterior palatal foramina and a long bony palate with prominent posterolateral palatal pits; the mesopterygoid fossa is short and wide, the alisphenoid lacks a dorsal flange, the accessory foramen ovale is absent, and the ectotympanic bullae are moderately inflated (Figure 27). These skull characteristics contrast with those of the other genera in the subfamily (*Cricetomys*, *Beamys*) and hence *Saccostomus* may be placed in a separate tribe, the Saccostomurini (see profile Subfamily Cricetomyinae).

Species in the genus are nocturnal and terrestrial, and live in burrows during the day. They are primarily granivorous; individuals collect seeds in their cheek pouches and deposit them in caches in burrows for later consumption. When food is abundant, they

Figure 27. Skull and mandible of *Saccostomus campestris* (HC 2435).

accumulate fat and increase in weight; when food is scarce during cool and dry weather, they become inactive and torpid and survive, partly, on accumulated fat reserves. Litter-sizes are comparatively large, with up to ten young/litter.

Two species are recognized. One species, *S. campestris*, has a large variation in chromosome number and may represent more than one species. The significance of such variation is uncertain. The second species, *S. mearnsi* from East Africa, was until recently considered as a subspecies of the more widespread *S. campestris*.

The species are distinguished by colour of body pelage, body size, number of chromosomes and geographic distribution.

D. C. D. Happold

Saccostomus campestris CAPE POUCHED MOUSE (SOUTHERN AFRICAN POUCHED MOUSE)

Fr. Rat à abajoues du Cap; Ger. Kap-Hamsterratte

Saccostomus campestris Peters, 1846. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 11: 58. Tete, Zambezi River, Mozambique.

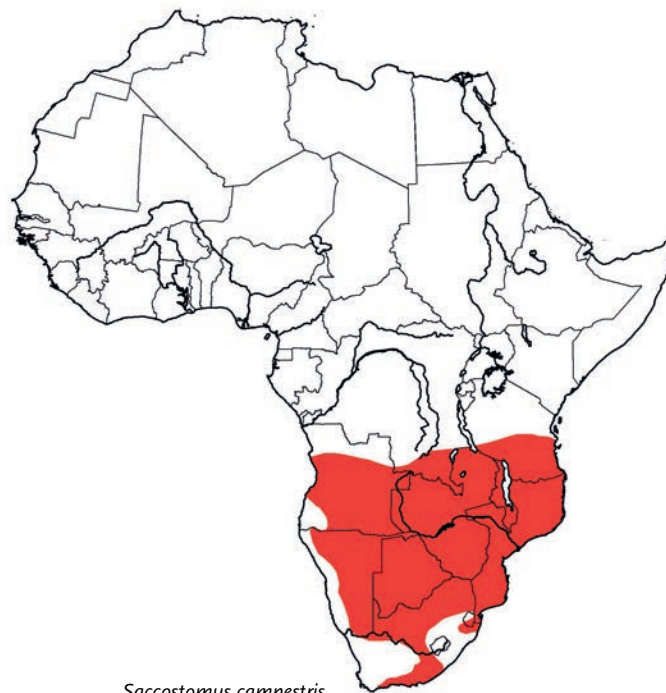

Taxonomy The species originally included *mearnsi* as a subspecies. The species, as currently defined, has considerable variation in chromosome numbers and in the structure of the chromosomes (Gordon & Rautenbach 1980, Gordon 1986). The variation is primarily geographic (see below), and more than one $2n$ number may occur in the same locality (Gordon 1986). There may be a complex of two or more species in southern Africa (Gordon 1986). Synonyms: *anderssoni*, *angolae*, *elegans*, *fuscus*, *hildae*, *lapidarius*, *limpopoensis*, *mashonae*, *pagei*, *streeteri*. Subspecies: none. Musser & Carleton (1993, 2005) suggest that *anderssoni* and *mashonae* deserve attention in respect of their relation to *campestris*. Chromosome number: $2n = 28$ to $2n = 50$, $FN = 46-62$ (details in Gordon 1986).

Description Small, stocky mouse with soft, thick coat and short tail. Pelage fine and dense. Dorsal pelage pale brownish-grey to grey with some black-tipped hairs along mid-dorsal line; hairs dark grey at base, medium grey or brownish-grey at tip. Colour of dorsal pelage varies geographically. Ventral pelage pure white. Colour of dorsal pelage clearly delineated from colour of ventral pelage. Chin, throat, lower cheek and base of muzzle white. Head broad, with rounded nose. Well-developed cheek pouches extend to near shoulders; very conspicuous when full of seeds. Ears short and rounded, held sideways from head. Fore- and hindlimbs white, short and stocky; four digits on forefeet, five digits on hindfeet. Tail short (ca. 44% of HB), without scales, dark above, white below, with sparse short bristles. Young animals are darker than adult animals. Body measurements of ♂♂ slightly larger on average than for ♀♀. Nipples: $3 + 2 = 10$.

Geographic Variation Sixteen chromosomal forms are recorded in southern Africa (Gordon 1986). There is a general decrease in $2n$ number from west (e.g. $2n = 46$ at the coast of KwaZulu-Natal Province, South Africa) to east (e.g. $2n = 30, 31, 32$ in W Namibia), but there are exceptions to this trend (e.g. $2n = 26-28$ in northern populations such as SE Angola and N Zimbabwe). In southern Africa, specimens from the drier western part of the range are paler in colour than those from the wetter eastern areas. Three colour forms – pale buffy-brown, blackish-grey and medium dark grey – recorded in Malawi; these may be partly associated with age (Hanney 1965).

Similar Species

S. mearnsi. HB on average larger; tail relatively longer; dorsal pelage dark grey to brownish-grey; ventral pelage dark grey, hairs sometimes with white tip (never pure white); East Africa; probably allopatric to *S. campestris* in C Tanzania (see also below).

Saccostomus campestris

Distribution Endemic to Africa. Zambezian Woodland and South-West Arid (Kalahari) BZs. Recorded from Angola, Zambia, Malawi, S Tanzania, Mozambique (mainly south of the Zambezi R.; records north of the river are sparse), SE DR Congo, C and N Namibia, Botswana, Zimbabwe and South Africa (SE Transvaal, C and N Free State, S KwaZulu-Natal, SW and E Cape Province). Not recorded from Lesotho (Lynch 1994). The northern boundary of the range of *S. campestris* in C Tanzania, where it adjoins the southern boundary of *S. mearnsi*, is uncertain.

Habitat Occurs in many types of woodland and grassland, and close to marshes. In Botswana, found in sandy regions, kopjes, open short grasslands, rocky kopjes, dry river beds, *Acacia* grasslands and mopane woodlands. In Malawi, found primarily in low altitude dry woodlands, but not on the high plateaux. In southern Africa, recorded in habitats where rainfall is 250 to over 1200 mm/annum, and from sea level to 1800 m. Sandy substrates with cover provided by bushes or open woodland are preferred habitat. In several parts of its range, burrows are dug in large abandoned termite mounds.

Abundance Widely distributed and locally common. Numbers fluctuate seasonally and individuals are rarely encountered during cool

dry weather. In South Africa, variations in density (0.31–1.70/ha) are related to the habitat, when the habitat was last burnt, and frequency of burning (Korn 1981). In *Acacia tortilis* savanna in north KwaZulu–Natal, densities varied from 0/ha to 3.8/ha, and in *Acacia nigrescens* savanna, from 0/ha to 1.8/ha (Swanepoel 1976). In thicket-clump savanna in Lengwe N. P., Malawi, mostly uncommon during the dry season (0–1/ha), but more abundant during and immediately after the wet season (up to 6/ha); during a ten-month period, they contributed 11% to the small mammal community, ranging from 0 to 1% in drier months and up to 28% in wetter months (Happold & Happold 1991).

Adaptations Terrestrial, scansorial and nocturnal. Excavates burrows in sandy soils or in termite mounds, or utilizes burrows made by springhares or Aardvarks. Burrows vary greatly in complexity and usually contain stores of seeds. When food is abundant, individuals store fat and put on weight. During the cool dry weather (or ‘winter’ in southern Africa), stored fat is metabolized and individuals lose weight; at this time, overall energy demands are reduced (Korn 1989), body temperature declines to 21–25 °C for 2–6 hours/day, there may be short bouts of daily torpor (Ellison & Skinner 1992), and overall activity is reduced. The stomach comprises a non-glandular forestomach and a distinctly differentiated glandular hindstomach; however, the relatively low density of bacteria in the forestomach suggests that bacteria do not contribute greatly to digestion and metabolism (Perrin & Kokkinn 1986).

Foraging and Food Predominantly granivorous. The diet includes a wide diversity of seeds. Seeds are gathered in the cheek pouches and taken to food caches in the burrow. The forefeet are used to help fill the cheek pouches. Seeds found in cheek pouches and in food caches include *Grewia monticola*, the umbrella thorn *Acacia tortilis*, sweet thorn *A. karroo*, scented thorn *A. nilotica*, camel thorn *Acacia erioloba*, nyala tree *Anthocercis zambesiaca*, red thorn *Acacia gerrardi*, *Combretum* spp., mopane *Colophospermum mopane*, sekelbos *Dicrostachys cinerea*, raisin bush *Grewia bicolor*, *G. flavescens*, *Burkea africana*, *Euclea crispa* and *Peltophorum africanum* (Smithers 1971, Swanepoel 1976, De Graaff 1981). Termites, grasshoppers and other insects are also eaten (De Graaff 1981). Kerley (1989) classified these Pouched Mice as ‘partially insectivorous granivores’ that forage widely from the burrows. The diet varies seasonally (Watson 1987): in Kruger National Park, during the dry season, it comprised 31% insects, 12% herbage and 57% seeds (n = 14), compared with 9% insects, 12% herbage and 79% seeds during the wet season.

Social and Reproductive Behaviour Solitary. Home-range in *Terminalia-Dichrostachys* grasslands of Kruger N. P., South Africa, is 1200 m² in control (unburnt) habitat and 1200–2800 m² in habitat burnt every three years (Korn 1981). Females in oestrus or pro-oestrus are aggressive and attack ♂♂ (Swanepoel 1976).

Reproduction and Population Structure Breeding and recruitment varies according to locality: Oct–Feb in KwaZulu–Natal (Swanepoel 1972), Oct–Apr in Transvaal (Rautenbach 1982), Jan–Apr in Botswana (Smithers 1971) and Feb–Apr in Zimbabwe (Smithers & Wilson 1979). These months are mostly during the warmer wetter months of the year. In Malawi, pregnant ♀♀ found in Apr/May (warm late wet season), Aug/Sep (cool dry season) and Dec/Jan (warm early wet season) (Hanney 1965). Litter-size also varies geographically, e.g. litter-size: 4.8 (2–8) in South Africa (Earl 1978); 7 (5–10) in Botswana (Smithers 1971); 6.7 (1–10, n = 7) in Zimbabwe (Smithers & Wilson 1979); and 5.1 (2–9, n = 10) in Malawi (Hanney 1965). Gestation: 20–21 days (Earl 1978). At birth, young fully furred, weight 2.8 g. Weaned Day 19–25 when 11 = 15 g. First litter Day 96 (Earl 1978). Females are spontaneous ovulators with a four-day cycle, without a postpartum oestrus (Westlin-Van Aarde 1988), and they exhibit a lactational anoestrus (Westlin-Van Aarde 1989). The energy demands of ♀♀ increase by 55% during pregnancy and by 110% during lactation (Perrin & Clarke 1987).

Predators, Parasites and Diseases Preyed on by Barn Owls *Tyto alba*, Grass Owls *T. capensis* and Giant Eagle-owls *Bubo lacteus*, and probably several small mammalian carnivores. They are hosts to a wide range of ectoparasites including 11 spp. of mites, 18 spp. of fleas and 4 spp. of ticks (details in De Graaff 1981). The nematode *Inermicapsifer madagascariensis* is a common endoparasite (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Widely distributed and locally common, and not threatened in natural habitats.

Mike Perrin

Saccostomus mearnsi MEARNS'S POUCHED MOUSE (EAST AFRICAN POUCHED MOUSE)

Fr. Rat à abajoues de Mearns; Ger. Mearns Hamsterratte

Saccostomus mearnsi Heller, 1910. *Smithson. Misc. Coll.* 54: 3. Changamwe, Coast Province, Kenya.

Taxonomy Morphological and chromosomal evidence indicate that *S. mearnsi* is distinct from *S. campestris* (Hubert 1978a, Gordon 1986). Synonyms: *cricetulus*, *isiolae*, *umbriventer*. Subspecies: none. Chromosome number: $2n = 40-42$ (Hubert 1978a), $FN = 40-42$.

Description Medium-sized, stocky mouse with soft, thick coat and short tail. Dorsal pelage pale to dark grey, dark brown or brownish-grey; hairs medium grey at base, grey or brownish-grey at tip. Flanks slightly paler. Ventral pelage grey (cf. *S. campestris*); some hairs tipped with white to give frosted appearance. Chin and base of muzzle whitish-grey. Head broad, with rounded nose and large eyes. Well-developed cheek pouches. Ears large and rounded, held sideways from head. Fore- and hindlimbs dark grey, short and stocky; four digits on forefoot, five digits on hindfoot. Tail short (ca. 50% of HB), thick at base, without scales, well covered with grey to brownish-grey hairs above, white below. Males often heavier than ♀♀. Nipples: probably $2 + 3 = 10$, as for *S. campestris*.

Geographic Variation None recorded.

Similar Species

S. campestris. Dorsal pelage medium grey; ventral pelage pure white; southern Africa as far north as C Tanzania.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ, and marginally around the Afromontane–Afroalpine BZ of Kenya. Recorded from SW Ethiopia, S Somalia, E Uganda, Kenya and N Tanzania. The southern boundary of the range is uncertain; current records suggest that *S. mearnsi* and *S. campestris* are allopatric in Tanzania.

Habitat Savanna; details of habitat preferences are poorly known. In C Kenya, abundant in woodland savanna on poorly drained soils and in shrubby thickets along seasonal watercourses and on kopjes.

Abundance Comprised ca. 80% of a small mammal community in the Laikipia District of C Kenya (Keesing 1998a). Population numbers fluctuated from 45/ha following heavy rains to 6/ha after a prolonged drought, with a 5-year average of 20/ha. Mearns's Pouched Mice were twice as abundant in areas from which large mammals had been excluded (Keesing 2000), presumably because of increased availability of food. In the few other areas from where they have been reported, *S. mearnsi* is less abundant than at Laikipia.

Adaptations Terrestrial and nocturnal, and strikingly slow-moving. Capable of digging deep burrows in hard soil with their strong legs and toes. Adults continue to grow after attaining reproductive maturity at ca. 45 g; old ♂♂ weigh as much as 120 g. See also *S. campestris*.

Foraging and Food Omnivorous. Diet varies seasonally; in the wet season, forbs and browse (82%) form the majority of the diet

*Saccostomus mearnsi*

with smaller amounts of seeds (9%) and arthropods (7%); in the dry season, the diet contains more seeds (33%) and arthropods (22%) and lesser amounts of forbs and browse (43%) (Neal 1984a). Diet varies at different localities (Keesing 1998a, Metz & Keesing 2001). Pouched Mice clip and consume both forbs and tree seedlings and often leave small piles of harvested vegetation. In cafeteria trials and in the field, they show strong preferences for certain forbs (e.g. *Commelina* spp., *Monsonia angustifolia*) and for the seeds and seedlings of *Acacia* trees. Because of their consumption of seeds and seedlings, they may influence the recruitment of *Acacia* trees (Keesing 2000). They appear to compete with ungulates for some food resources, since the removal of ungulates results in rapid increases in their numbers (Keesing 1998b).

Social and Reproductive Behaviour Mostly solitary, living alone in burrows constructed in termite mounds, under shrubs and at the bases of trees. At high population densities, however, Pouched Mice live in close proximity, occasionally sharing burrow entrances and possibly entire burrow systems with conspecifics (Keesing 1998a). In encounters between pairs of same-sex individuals, both ♂♂ and ♀♀ exhibited a number of behaviours typical of more social rodents (e.g. vocalizations, allogrooming, appeasement). Based on data from long-term trapping records, ♀♀ appear to be territorial, while the home-ranges of ♂♂ are broadly overlapping and superimposed on those of ♀♀ (Keesing & Crawford 2001). Home-range of ♂♂: 0.21 ± 0.02 ha; home-range of ♀♀: 0.06 ± 0.01 ha.

Reproduction and Population Structure Reproduction is seasonal in C Kenya: almost all adult ♀♀ are in breeding condition

in Aug–Nov following the wet season (Apr–Jul), while only 10% are in breeding condition during the dry season (Jan–Mar). At least 85% of adult ♂♂ remain in breeding condition throughout the year. Litter-size: 3–5. Gestation, ontogeny and time to maturity unknown (but see *S. campestris*).

Predators, Parasites and Diseases Predators unknown. Reported to be hosts for juvenile stages of some *Rhipicephalus* ticks. However, larval ticks experimentally placed on mice were groomed off and never recovered, suggesting that these mice are poor hosts for juvenile ticks (F. Keesing unpubl.).

Conservation IUCN Category: Least Concern.

Subfamily DELANYMYINAE – Delany's Swamp Mouse

Delanymyinae Musser & Carleton, 2005. *In* Mammal Species of the World, 3rd Ed., p. 934.

The subfamily Delanymyinae contains only a single genus and species, *Delanymys brooksi*, endemic to Western Rift Mts in East Africa. This very small, gracile mouse possesses an exceptionally long and semi-prehensile tail and large hindfeet with slender toes. Such traits impressed Hayman (1962a), who described the species as convergently resembling Eurasian birch mice (*Sicista*, Dipodoidea); similar convergence in body form is also seen in the Sundaic and Sulawesi murine *Haeromys* (Musser 1990). Like these mice, *Delanymys* is an expert climber, adept at negotiating slim stems and branches and filling a semi-arboreal, granivorous niche.

Until recently, *Delanymys* had been grouped with *Petromyscus* in Petromyscinae, but the two genera differ in many essential features. In *Delanymys*, the tail is twice as long as the head and body and semi-prehensile (less than to moderately longer in *Petromyscus*), and the hindfoot is long and narrow (short and broad in *Petromyscus*). The cranium of *Delanymys* possesses a very short rostrum (long and slender in *Petromyscus*), narrow interorbital constriction (broad in *Petromyscus*), narrow zygomatic plate with a shallow dorsal notch (plate broad and notch deep in *Petromyscus*), and large subsquamosal foramen (closed in adult *Petromyscus*). Examples of *Delanymys* have a short bony palate, in contrast to the long palate that projects as a prominent shelf behind the third molars in *Petromyscus*. An alisphenoid strut is absent in *Delanymys* (present in *Petromyscus*), and the carotid circulation is fully derived, lacking supraorbital and infraorbital arteries and the accompanying squamosal-alisphenoid groove and sphenofrontal and stapedial foramina (partially derived in *Petromyscus*, which retains the infraorbital artery and a large stapedial foramen). The molars in both genera are brachydont and cuspidate, but those of *Delanymys* have anterolophids and mesolophids (all absent in *Petromyscus*), and its M³ is relatively large with an occlusal pattern that resembles M² (M³ very small in *Petromyscus*, with C-shaped occlusal pattern unlike M²) (Figure 28).

The unique morphology of *Delanymys*, especially characters of the molar dentition, has generated various interpretations of its phylogenetic placement. Hayman (1962) regarded *Delanymys*

as morphologically close to *Petromyscus* and considered both to be dendromurines, and Petter (1967) acknowledged this relationship by classifying *Delanymys* and *Petromyscus* in Petromyscinae, separate from Dendromurinae. Others have emphasized resemblances between *Delanymys* and *Mystromys* or have viewed *Delanymys* as a structural link between *Mystromys* and typical Dendromurinae (Lavocat 1964, Verheyen 1965a). These conflicting views hinge, in part, on disputes over the origin and homology of the lingual cusp on the upper molars of *Delanymys* and *Petromyscus*, believed to represent either the

Figure 28. Skull and mandible of *Delanymys brooksi* (skull - RMCA 96-038-M-3386 with some detail from BMNH 61.1610; mandible after Verheyen (1965a); upper cheek teeth RMCA 96.038-M-3385).

protocone (Petter 1967) or a neomorphic acquisition comparable to those of dendromurines and certain Miocene fossils (Lavocat 1964, Jaeger 1977b). Aside from the questionable phylogenetic significance of these lingual cusps, *Delanymys* and *Petromyscus* share no other derived features that persuasively justify their joint membership in Petromyscinae as a natural group (Carleton & Musser 1984, Denys 1994a). Further, the dual retention of mesolophs(ids) and longitudinal enamel connections on its molars marks *Delanymys* as unique among living African Muroidea and suggests that it

represents a relictual descendant from a very early radiation of the superfamily within the continent. Musser & Carleton (2005) erected the subfamily Delanymyinae to contain the genus and urged further inquiry to illuminate its phylogenetic relationships.

Fossils of the Delanymyinae, represented as the extinct *Stenodontomys*, are known from the early Pliocene to the early Pleistocene of southern Africa (Pocock 1987, Senut *et al.* 1992, Denys 1994).

Guy G. Musser & Michael D. Carleton

GENUS *Delanymys* Delany's Swamp Mouse

Delanymys Hayman, 1962. Rev. Zool. Bot. Afr. 65: 1–2. Type species: *Delanymys brooksi* Hayman, 1962.

Montotypic genus. In the description of the holotype, Hayman (1962) placed *Delanymys* in the subfamily Dendromurinae. An alternative view based on the 'longitudinal crest' in the molar row, is that it is closely related to *Mystromys* (subfamily Mystromyinae) (Lavocat 1964). Petter (1967) interpreted the molar structure of *Delanymys* as very similar to that of *Petromyscus* (both have an additional lingual cusp on M¹ and M², which is connected to other cusps by a longitudinal ridge); he placed both genera in the subfamily Petromyscinae, even though they are very different in other skull characters, external morphology, habits and distribution. The current opinion seems to be that *Delanymys* is far removed from the Dendromurinae, but whether the similarities to *Petromyscus* are phylogenetic or due to convergence is uncertain. Further details are given in the subfamily and species profiles.

Fritz Dieterlen

Delanymys brooksi DELANY'S SWAMP MOUSE

Fr. Souris palustre de Delany; Ger. Delanys Sumpfklettermaus

Delanymys brooksi.

Delanymys brooksi Hayman, 1962. Rev. Zool. Bot. Afr. 65: 1–2. Echuya (or Muchuya) Swamp, near Kanaba, Kigezi, SW Uganda.

Taxonomy See genus profile. Synonyms: none. Chromosome number: not known.

Description Very small climbing mouse with an extremely long tail and long hindfeet. Pelage long (8–10 mm). Dorsal pelage warm russet or rufous to hazel-brown; hairs dark slate-grey on basal two-thirds, russet or rufous on terminal one-third. Long black guard hairs (each with subterminal buff band) project well above pelage tending to give a generally darker colouration. Ventral pelage warm buff; hairs mostly ca. 7 mm, with tuft of long white hairs surrounding the urinogenital opening in both ♂♂ and ♀♀. Throat with longitudinal patch of pure white hairs. Eyes surrounded by short black hairs; black patch on nasal region between eyes and rhinarium. Lips with very long (20–25 mm) vibrissae. Ears relatively large, round, with well-developed ear folds, and long (5–7 mm) hairs in places. Upperparts of fore- and hindlimbs with dark hairs; inner surfaces with whitish hairs. Small tuft of white hairs on each wrist, thought to have a tactile function (Dieterlen 1969b). Fore- and hindfeet very small with long

digits and long curved claws (except for vestigial Digit 1 on forefoot, which has small nail); Digits 3 and 4 very long, Digits 2 and 5 long but shorter than 3 and 4. Tail extremely long (ca. 180% of HB), thin, almost hairless with small scales forming ring-like patterns. Males on average slightly smaller than ♀♀. Palatal ridges: three antemolar and four intermolar. Skull: rostrum very short, palate short, mesopterygoid fossa completely open anteriorly, zygomatic plate narrow; see also subfamily and genus profiles. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

Dendromus spp. Black mid-dorsal stripe in some species; tail long but mostly relatively shorter; more widespread distribution for most spp.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from a small area bordering the Albertine Rift Valley in

Delanymys brooksi

SW Uganda, W Ruanda and E DR Congo (near L. Kivu). The most northern and eastern locality is Muchuya Swamp (01°15'–01°18' S; 29°47'–29°51' E), near Kanaba in Uganda where the type specimen was found in 1961 (Hayman 1962a). The southernmost record is Kitabi in Rwanda (02°34' S, 29°26' E; 2200 m). The geographic range may also include the area from the volcano region north of L. Kivu southwards to the Itombwe Mts north-west of L. Tanganyika.

Habitat Most individuals have been found in high altitude marshes, rich in plant species, at altitudes of 1700–1760 m. The typical habitat is swamp where sedge (*Cladium mariscus*) is standing in water, and the vegetation in the shallows is elephant grass (*Pennisetum*), *Hyparrhenia* grass and non-grassy plants such as *Abutilon*, *Rubus*, *Acanthus* and *Impatiens*. The medium height of such vegetation is 1.5–2.0 m. A few individuals have been found in non-marshy habitats such as dense grassy vegetation (Mt Gahinga [2700 m] and Mt Karisoke [3100 m]), and between ferns in a plantation of *Eucalyptus* at Kitabi (2200 m) (Van der Straeten & Verheyen 1983).

Abundance Using an enclosure and removal method, Delany's Swamp Mice comprised 6.2% of all small mammals ($n = 355$; >20 species) (Dieterlen 1967a, b). In non-marshy habitats, they are extremely rare (Dieterlen 1967a; Van der Straeten & Verheyen 1983) and it can be assumed that even in marshes they are not numerous, except in a few locations.

Adaptations Nocturnal and arboreal on grass stems. The fore- and hindfeet are extremely well adapted for climbing on the stems of grass and other low herbaceous plants in marshes and grasslands. The forefoot has a rudimentary Digit 1 (thumb), four relatively long fingers (Digits 2, 3, 4 and 5), five large plantar pads and numerous small but prominent tubercles on palm and fingers. When grasping, the proximal pads and the thumb form fit tightly against the flexible fingers. The fingers can be spread widely for climbing, and closed

tightly to prevent sliding down the plant. The hindfeet are unusually long (ca. 30% of HB) and have six plantar pads; Digits 2 to 5 are long, and Digit 1 is shorter but capable of being spread sideways. Digit 5 is especially long and strong, and is opposable. The long prehensile tail is used to provide balance when climbing, and the distal end can curl around stems to provide support. In these respects, the adaptations of the feet are very similar to those of *Dendromys* spp. The spreading ability of digits of the fore- and hindfeet is also very important when walking on the muddy ground.

Foraging and Food Vegetarian. Stomach contents ($n = 2$) contained only the whitish pulp of farinaceous seeds, probably from grasses, without any green material or animal remains. Captive animals preferred seeds, especially sorghum; water was permanently available and used not only for drinking but also for regular defecation (Dieterlen 1969b).

Social and Reproductive Behaviour Delany's Swamp Mice are gentle mice, and individuals of both sexes live peacefully together in captivity. In this respect, they differ from *Dendromys* spp., which tend to show aggressive behaviour.

Reproduction and Population Structure Embryo number: 3 ($n = 2 \text{ ♀} \text{ ♀}$); one ♀ found in a nest had four young. At birth, young are altricial. At Day 10, the eyes are closed, the incisors have not yet erupted and the short hazel-coloured pelage is brighter than in adults, WT = 2.5–2.7 g. Individuals in captivity did not reproduce.

Predators, Parasites and Diseases A dead individual found near the nest of an African Grass-owl *Tyto capensis* in E DR Congo suggests these owls may be potential predators (James Chapin, in Hayman 1963).

Conservation IUCN Category: Vulnerable. Schlitter (1989) classified the species as Rare, and hence of some conservation concern. The small geographical range has experienced considerable habitat destruction in recent years and has a very high human population density.

Subfamily DENDROMURINAE – African Climbing Mice

Dendromurinae G. M. Allen, 1939. Bull. Mus. Comp. Zool., Harv. Coll. 83: 349.

The Dendromurinae encompasses a small muroid radiation (six genera and 24 species *sensu* Musser & Carleton 2005) whose living representatives are indigenous to sub-Saharan Africa. Although few in number, members of the six genera are highly diversified in their morphology, behaviour and ecology. *Dendromus* and *Megadendromus*, though occasionally active at ground level, are primarily adept climbers of slender grasses and shrubs where they forage and construct nests; accordingly, they are found in habitats where grasses and shrubby vegetation predominate (marshes, savannas, forest edges, alpine bamboo and heath zones). They are largely omnivorous, feeding upon seeds, berries and insects. In contrast, *Steatomys* is terrestrial, dwells primarily in savanna habitats, accumulates copious fat reserves during periods of abundant food and can aestivate in response to unfavourable environmental conditions. *Malacothrix*, endemic to the South-West Arid BZ, is terrestrial, granivorous and gerbil-like in certain aspects of its morphology and habits. *Dendroprionomys* and *Prionomys* are arboreal and insectivorous inhabitants of lowland evergreen rainforest. All are nocturnal.

Diagnostic features that unite so heterogeneous a group are few: first and second upper molars consist of bicuspid laminae, with a lingual accessory cusp adjacent to the middle lamina of M^1 and front lamina of M^2 . M^3 and M_3 are tiny and single-rooted. Each upper incisor has a single deep groove (except *Prionomys*). Other characters include: infraorbital foramen wide and ovoid; zygomatic plate narrow; dorsal notch indistinct or shallow; masseteric tubercle prominent; carotid circulatory pattern partially derived (sphenofrontal foramen and squamosal-alisphenoid groove absent, stapedial foramen spacious); postglenoid foramen large and subsquamosal fenestra present, middle lacerate foramen small; strut of alisphenoid bone present,

delineating an accessory foramen ovale; and tegmen tympani reduced, not contacting the squamosal (Petter 1966c, Dieterlen 1971, Carleton & Musser 1984) (Figure 29).

Dendromurines are small to very small in size, and the genera vary substantially in external characters. The pelage is short, soft and slightly woolly (*Dendromus*, *Megadendromus*), short and velvety (*Dendroprionomys*, *Prionomys*), or dense and silky (*Malacothrix*); a black, mid-dorsal stripe is well developed in *Megadendromus* and some *Dendromus*. Compared with body size, the ears are small (*Prionomys*), moderately large (*Dendromus*, *Megadendromus*) or exceptionally large (*Malacothrix*). Relative to the head and body, the tail may be longer (*Dendromus*, *Prionomys*), about equal to (*Megadendromus*) or conspicuously shorter (*Malacothrix*, *Steatomys*); and its surface naked to thinly haired and visibly scaly (*Dendromus*, *Megadendromus*, *Prionomys*) or moderately to thickly haired with caudal scales inconspicuous (*Malacothrix*, *Steatomys*). The forefoot may possess only three functional digits (Digits 2, 3 and 4; Digits 1 and 5 present but small and non-functional; *Dendromus*, *Megadendromus*), four digits (Digits 2, 3, 4 and 5; *Malacothrix*, *Steatomys*), or four plus a stubby but definitive Digit 1 (*Dendroprionomys*, *Prionomys*). *Malacothrix* has four digits on the hindfoot, the other genera have five digits (Figure 30). In certain dendromurines, the claw is replaced by a nail on Digit 1 of the hindfoot (*Dendromus*, *Dendroprionomys*, *Prionomys*) and on Digit 5 (some *Dendromus*, *Megadendromus*). Palmar and plantar surfaces are naked (*Dendromus*, *Megadendromus*, *Dendroprionomys*, *Prionomys*), hairy over the proximate third (*Steatomys*), or densely furred so that the plantar pads are obscured (*Malacothrix*).

The skull typically possesses a long and slender rostrum (most genera) or only moderately long and wide (*Steatomys*). The interorbital region is strongly constricted with smooth edges (*Dendromus*, *Malacothrix*, *Megadendromus*, *Steatomys*) or moderately wide with a weak postorbital ledge (*Dendroprionomys*, *Prionomys*). Anterior palatal foramina are slender and long, posterior margins reaching middle of first upper molars (*Dendromus*, *Malacothrix*, *Megadendromus*, *Steatomys*), or short and wide, the posterior margins set notably anterior to molar rows (*Dendroprionomys*, *Prionomys*). The auditory bulla is inflated in *Malacothrix* and *Steatomys* relative to other genera. Most genera have orthodont or opisthodont upper incisors, but in *Prionomys* the incisors

Figure 29. Skull and mandible of *Dendromus melanotis* (RMCA 38416).

Figure 30. Right hindfoot of (a) *Dendromus* sp., (b) *Dendroprionomys rousseloti*, (c) *Prionomys batesi* to show relative sizes of Digit 1 and Digit 5 (after Petter 1966b). Hindfeet drawn to same length for each species.

are slightly pro-odont. The upper molar rows are parallel in most genera but divergent anteriorly in *Steatomys*; occlusal surfaces are cuspidate, or somewhat laminate in *Steatomys*; cusp rows of M^1 and M_1 lack longitudinal enamel crests in most genera, interconnecting longitudinal crests present in *Malacothrix*; posterior cingulum of M^1 and M^2 is small (*Dendroprionomys*, *Malacothrix*, *Prionomys*), laminar (*Steatomys*), large and oblong (*Dendromus*), or exceedingly large and forming an oblong cusp (*Megadendromus*).

In view of the variability and diversity of dendromurines, the employment of the taxon Dendromurinae in muroid classifications has suggested a 'waste-basket' for African taxa of highly specialized morphology and hence obscure relationships. The subfamily has been thought to include *Lophuromys* (Alston 1876), *Leimacomys* (Thomas 1897, and others), *Beamys* and *Saccostomus* (Allen 1939), *Petromyscus* (Ellerman 1941, Simpson 1945) and *Deomys* (Simpson 1945), genera that are now affiliated with four other muroid subfamilies (Cricetomyinae, Deomyinae, Leimacomyinae, Petromyscinae). While others have noted that Dendromurinae as arranged in former classifications is polyphyletic (e.g. Rosevear 1969, Carleton & Musser 1984), the cladistic analysis by Denys *et al.* (1995), based largely on dental traits, has convincingly demonstrated that the subfamily has a polyphyletic origin. However, strict interpretation of their study would exclude *Prionomys* and *Dendroprionomys* from the core dendromurines (*Dendromus*, *Malacothrix*, *Megadendromus*, *Steatomys*), a hypothesis that warrants continued testing in a broader systematic context.

As with the uncertainty surrounding its generic contents, Dendromurinae has been alternatively associated with murids (Miller & Gidley 1918, Simpson 1945) or cricetids (Allen 1939, Misonne 1974), and even ranked as a separate family (Chaline *et al.* 1977). In part, this vacillation hinges on the homology of the lingual accessory cusp (enterostyle) on the lamina of the upper molars,

whether a presumptive $t4$ corresponding to that in the murid triserial arrangement or a neomorphic acquisition evolved in parallel from a cricetid stock. Phylogenetic implications issuing from recent studies of morphology (Breed 1995, Denys *et al.* 1995) and DNA sequences (Verheyen *et al.* 1995, Michaux *et al.* 2001, Jansa & Weksler 2004) provide stronger vindication for the latter interpretation and support closer affinity of dendromurines to other archaic African muroids, here arranged in Nesomyidae, than to murids proper.

Although living species are today restricted to the sub-Saharan region, the subfamily was more widespread in the Tertiary. Fossils are known from the late Miocene of Africa's Mediterranean rim (Ameur 1984), the Iberian Peninsula (Aguilar *et al.* 1984) and the Arabian Peninsula (De Bruijn & Whybrow 1994, De Bruijn 1999). Certain extinct genera from the middle Miocene of North-West Africa, Pakistan and Thailand have been referred to Dendromurinae (e.g. Lindsay 1988, Mein & Ginsburg 1997), but their identification as such is disputed (e.g. Tong & Jaeger 1993, Wessels 1996). The earliest indisputable dendromurine thus far documented (*Ternania*) appears in the middle Miocene of Kenya, about 14 mya (Tong & Jaeger 1993). Representatives of *Dendromus* appear in the late Miocene of Ethiopia (Geraads 2001), and *Steatomys* is known from the late Miocene of Namibia (Senut *et al.* 1992). These genera, as well as *Malacothrix*, are commonly and widely recorded from the late Pliocene to the Quaternary in southern and eastern Africa (e.g. Jaeger 1979, Denys 1987a, b, 1994, Pocock 1987, Avery 1996, 1998).

Four of the six dendromurine genera are monospecific (*Dendroprionomys*, *Malacothrix*, *Megadendromus*, *Prionomys*), but *Dendromus* (ten species) and *Steatomys* (eight species) each contain several species and may prove to be even more diverse after further systematic study.

Guy G. Musser & Michael D. Carleton

GENUS *Dendromus* African Climbing Mice

Dendromus Smith, 1829. Zool. J. London, 4: 38. Type species: *Dendromus typus* Smith, 1829 (= *Mus mesomelas* Brants, 1827)

The genus *Dendromus* contains 11 or 12 species of small climbing mice distributed throughout sub-Saharan Africa. Most species occur in southern, central and East Africa; only one, with a very disjunct distribution, is recorded from West Africa. Three species have wide distributions; most have a small distribution, and others are restricted to one or more widely scattered locations. Typical habitats are long grasslands, bracken, dense scrub, grassy wetlands, and subalpine or alpine vegetation. In some regions, several species are sympatric (e.g. Kivu, E DR Congo; Dieterlen 1971).

Species in the genus are characterized by delicate build, small size, soft brown or reddish-brown pelage, long thin tail (100–160% of HB, depending on the species) and specialized feet. Several species have a black mid-dorsal stripe and one species (*D. lovati*) has three black stripes. The forefoot has only three well-developed digits (Digits 2, 3 and 4); Digit 1 is extremely reduced and Digit 5 is short. The hindfoot has five elongated digits; Digits 2, 3 and 4 are long and slender, Digit 1 is reduced but functional, and Digit 5 is long and semi-opposable and widely separated from other digits (Figure 30). Some species have a nail on Digit 5 of the hindfoot, rather than a claw. Skull characters

Skeleton of *Dendromus*.

include: small in size, delicate build, rostrum narrow, zygomatic plate narrow with the masseteric knob at lower corner of the plate, anterior palatal foramina extending to middle row of M^1 , supraorbital ridges absent and auditory bullae comparatively well developed. Upper incisors small, slightly opisthodont, each with single longitudinal groove. Cheekteeth small; M^2 about half size of M^1 ; M^3 very small; cusps biseral (two cusps in each row), with additional small lingual cusp on middle lamella of M^1 and (to a lesser extent) on M^2 .

Most species of *Dendromus* climb using the long digits of the forefeet and hindfeet. The opposable Digit 5 of the hindfeet (which can be

opposed to contact Digit 1) and the semiprehensile tail are especially important for climbing and balancing on twigs and grass stems. Some species tend to be more terrestrial than others. They feed primarily on seeds and are mostly nocturnal. Some species, kept in captivity, tend to rather aggressive to conspecifics and to other co-habiting species.

Systematically, *Dendromus* is one of the most difficult genera of African rodents. Rosevear (1969) records that over 50 forms have been given names, and that eight species have been recognized. Bohmann (1942) disposed of these forms in three 'Rassenkreisen', roughly equivalent to what are now considered as *D. mesomelas*, *D. melanotis*

Table 16. Species in the genus *Dendromus*, arranged alphabetically. (n. d. = no data.)

| Species | HB mean (range) (mm) | T mean (range) mm [% HB] | Colour of dorsal pelage | Colour of ventral pelage | Mid-dorsal stripe [width of stripe] | Claw/nail on Digit 5 of hindfoot | Notes |
|-----------------------|---------------------------|-------------------------------------|---|--|---|----------------------------------|--|
| <i>D. insignis</i> | 80.1 (68–96) | 97 (84–113) [120%] | Rich brown, reddish or buff | Buff-grey; grey at base | One. Back of head to rump [4 mm] | Claw (short) | Montane areas of eastern Africa. Chin/throat white. Pelage long and dense |
| <i>D. kahuziensis</i> | (77, 82) | (120, 132) [157%] | Dark brown, dusky | White; dark grey at base | One. Forehead to base of tail [8 mm] | Claw | Mt Kahuzi, E Zaire only. Chin, throat and chest white |
| <i>D. lovati</i> | 74 (57–95) | 73 (57–87) [100%] | Warm greyish-brown | Greyish; grey at base | Three. Middle stripe 40–50 mm long, rump to neck; outer stripes 25–30 mm long, rump to shoulders [n.d.] | Nail | Afroalpine, Ethiopia. Black stripe on head from between eyes to back of head |
| <i>D. melanotis</i> | 68 (56–81) ^a | 90 (76–108) ^a [120–130%] | Medium-brown to rufous-brown; flecked with grey | Greyish; grey at base | One. Shoulder to base of tail [3–4 mm] | Nail | Widespread in southern and eastern Africa. Common |
| <i>D. mesomelas</i> | 76 (69–80) ^a | 99 (91–105) ^a [130–140%] | Rufous-brown; woolly texture | Off-white; hairs dark at base with whitish tip | One. Shoulder to base of tail (absent in some) [variable] | Claw | Widespread in southern and eastern Africa. Common |
| <i>D. messorius</i> | 63.5 (60–68) | 88.6 (72–95) [140%] | Gingery-brown | Pure white | Absent (Occasionally faint brown in West Africa) | Claw | Mostly West Africa; often found in banana plants |
| <i>D. mystacalis</i> | 60.2 (55–65) ^a | 84.8 (75–95) [140–160%] | Bright rufous-brown | Pure white | One. Shoulder to base of tail [variable] | Claw | Widespread in southern and eastern Africa |
| <i>D. nyasae/kivu</i> | 74 (64–80) | 92 (84–105) [124%] | Rich brown | Silvery-white; grey at base | One. Neck to base of tail [2–3 mm] | Claw (short) | Albertine Rift Valley 1300–4200 m |
| <i>D. nyikae</i> | 66.8 (50–78) ^a | 86.4 (80–93) [130–160%] | Pale to dark cinnamon | Creamy-white; white at base (sometimes grey) | One. Shoulder to base of tail [variable] | Nail | Mostly eastern Africa; higher altitudes. White subauricular patch |
| <i>D. oreas</i> | 69.3 (60–74) | 95.3 (89–104) [135%] | Medium brown | Dark rufous to greyish-yellow; dark at base | One. Indistinct; mid-back to base of tail [3–4 mm] | Claw | Cameroon Mts only. White patches on chin, throat and chest |
| <i>D. vernayi</i> | 63.6 (60–66) | 82.0 (80–84) [130%] | Ochre- to cinnamon-brown; long and silky | Pinkish-buff to grey; grey at base | One [4.5 mm] | n. d. | Chitau, Angola. Rare. White patch on throat and axillary region |

^a Males only.

and *D. mystacalis*; but this reduction created additional problems. The genus as a whole possesses a very homogeneous morphology with respect to skull and dentition, but a great variability of pelage colour and pattern, so that classifying the species often depends on rather few details (Heim de Balsac & Lamotte 1958, Dieterlen 1971). Musser & Carleton (2005) recognize 12 species and list 44 synonyms for the whole genus. The distributional limits of many species are unresolved, and karyological information is unavailable for most species. The

genus is in need of further study and revision. Here, 11 species are recognized; the twelfth species of Musser & Carleton (2005), *D. leucostomus*, is placed as a synonym of *D. melanotis*.

The species are distinguished by body size, pelage colour, presence or absence and form of the mid-dorsal stripe, presence of nail or claw on Digit 5 of hindfoot, and distribution (Table 16).

Fritz Dieterlen

Dendromus insignis MONTANE AFRICAN CLIMBING MOUSE

Fr. Souris arboricole des montagnes; Ger. Gebirges-Klettermaus

Dendromus insignis (Thomas, 1903). Ann. Mag. Nat. Hist., ser. 7, 12: 341. Nandi, Kenya.

Taxonomy Originally described in the genus *Dendromys*. This species belongs to the *mesomelas* species-complex, although there is some doubt about which forms may be included within *insignis* (Thomas 1916b, Bohmann 1942, Ellerman *et al.* 1953). The holotype may be unrepresentative of the species as a whole, and its relationship to *mesomelas* is uncertain. According to Musser & Carleton (2005), most literature references to *D. mesomelas* in montane habitats north of the southern African sub-region prior to 1991 actually represent either *D. insignis* or *D. nyasae* (*kivu*), both of which may co-occur in the Albertine Rift Valley mountains. Synonyms: *abyssinicus*, *kilimandjari*, *percivali*. Subspecies: none. Chromosome number: not known (identity of Matthey's [1967, 1970] specimens is questionable).

Description Very small climbing mouse with broad mid-dorsal stripe; the largest species of *Dendromus*. Pelage long (8–9 mm) and dense; shows considerable individual variation (see below). Dorsal pelage rich brown tending to reddish or buff; hairs grey at base, brown at tip. Underfur dark grey, which may provide greyish tinge to pelage. Broad (ca. 4 mm) black mid-dorsal stripe from back of head to base of tail. Ventral pelage and flanks mainly buff or buffy-grey; hairs grey at base, buff at tip. Small area of chin and throat pure white. Indistinct black longitudinal stripe (ca. 10–20 mm in length) on head. Ears with short brown or black hairs. Hindfeet silver-grey. Hindfoot with five digits; Digit 1 short with nail, Digit 5 long with claw. Tail very long (ca. 120% of HB, but relatively short compared with other *Dendromus* spp.), dark brown above, much paler below with long silvery-grey hairs. Nipples: 2 + 2 = 8.

Geographic Variation Pelage variable: longer on individuals living above 2000 m; darker in colour in young and subadults than in adults; ventral colouration tends to be more variable than dorsal colour.

Similar Species

D. nyasae (*kivu*). HB on average slightly smaller (mean 73.4 mm); tail on average slightly shorter (mean 91.8 mm) but of similar relative length (ca. 124% of HB); mid-dorsal stripe 2–3 mm wide, from neck to base of tail; pelage not as dense.

D. mesomelas. HB on average smaller (mean 74–76 mm); tail on average longer (mean 99–103 mm) and relatively longer (130–140% of HB); narrower mid-dorsal stripe, sometimes absent; pelage woolly; larger geographic range.

Dendromus insignis

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of eastern Africa. Recorded from the Rwenzori Mts (up to 4500 m; Misonne 1963, Verschuren *et al.* 1983); Virunga Range and Mitumba Mts west of L. Kivu (1700–3300 m; Dieterlen 1976a); Mt Kenya (2300–4300 m; Hollister 1919), Matthews Range, Mau Escarpment, Aberdare Range, Mt Kilimanjaro (3500–4700 m) and Uluguru Mts (Bohmann 1942, F. Dieterlen unpubl.). The total range of the species is uncertain because of the uncertain taxonomic status of some related forms and lack of material from large areas. Maybe sympatric with *D. nyasae* (*kivu*) at some localities in the mountains of the Albertine Rift Valley (Dieterlen 1971, 1976a, as *D. mesomelas* *kivu*).

Habitat In the cultivated regions near L. Kivu, DR Congo (1500–2000 m), lives with other species of *Dendromus* in open comparatively dry dense grassy areas (Dieterlen 1971) and, less frequently, in marshes and moist herbaceous vegetation. Also occurs in sparse bamboo and secondary forest above 2000 m, and in wet grass and

herbaceous vegetation in sub-alpine and alpine zones above 3000 m (Kingdon 1974, Dieterlen 1976a).

Abundance May be abundant at lower altitudes, but becomes progressively less common with increasing altitude.

Adaptations Probably nocturnal and diurnal. Although comparatively large and heavy (15 g) and often found on the ground, these mice are agile climbers. The opposable Digit 5 of hindfoot and the semi-prehensile tail are used to provide support when climbing. More terrestrial than many species of *Dendromus*. Because of its terrestrial habits, this species is trapped more often than other *Dendromus* spp. Most nests seem to be on the ground or in burrows.

Foraging and Food Omnivorous and/or insectivorous. Two stomachs contained remains of well-chewed seeds (including sorghum), reddish berries and arthropods (Dieterlen 1971, 1976a).

Social and Reproductive Behaviour No information, but it is presumed that individuals are mostly or entirely solitary.

Reproduction and Population Structure Near L. Kivu, most young born in the wet season between Sep and May. Gestation: not known (although probably similar to *D. nyasae* [kivu]). Embryo number: 4 (n = 3). Young extremely altricial at birth; postnatal development is slow. Sex ratio: 69 : 31% (ca. 7 : 3; n = 48). In most respects, reproduction and population structure appear to be similar to *D. nyasae* (kivu) (Dieterlen 1971).

Predators, Parasites and Diseases Small carnivores, birds and snakes are potential predators. Predatory ants are certainly a great danger for young in the nest during the first three weeks of life, especially when nests are on the ground or in burrows.

Conservation IUCN Category: Least Concern.

Dendromus kahuziensis KAHUZI AFRICAN CLIMBING MOUSE

Fr. Souris arboricole du Mont Kahuzi; Ger. Kahusi-Klettermaus

Dendromus kahuziensis Dieterlen, 1969. Z. Säugetierk. 34: 348–349. SSW slopes of Mount Kahuzi, Kivu, DR Congo. 2100 m.

Taxonomy Very distinct species of *Dendromus* with an extremely long tail, broad mid-dorsal stripe and long gracile rostrum. Systematic relationships unknown. Only two specimens known. Synonyms: none. Chromosome number: not known.

Description Small climbing mouse with a wide mid-dorsal stripe and very long tail; a comparatively large species of *Dendromus*. Dorsal pelage dusky dark-brown; hairs greyish-black with medium brown tip. Mid-dorsal blackish stripe from head (at level with the eyes) to base of tail; stripe broad (ca. 8 mm), broader than in other species of *Dendromus*. Flanks paler; hairs with pale brownish tip. Chin, throat and chest white; hairs dark grey at base. Head with pale brown on cheeks and behind ears. Eyes with black rings, which extend anteriorly on to nasal region. Ears with sparse short black and reddish hairs. Forefoot with three long digits; Digit 1 rudimentary, Digit 5 minute. Hindfoot with five digits; Digit 1 short without nail or claw, Digit 5 long and opposable with long claw. Tail very long (ca. 157% of HB), comparatively longer than in other *Dendromus* spp., with short dark bristles, darker above, paler below. Skull with long nasals and rostrum. Nipples: not known.

Geographic Variation None recorded.

Dendromus kahuziensis

Similar Species

- D. insignis*. HB similar; tail shorter (ca. 80 mm and ca. 120% of HB); mid-dorsal stripe broad (ca. 4 mm) from back of head to base of tail.
- D. nyasae* (kivu). HB slightly smaller; tail shorter (84–105 mm ca. 124% of HB); long mid-dorsal stripe (2–3 mm wide) from behind head to base of tail.
- D. mystacalis*. HB smaller; tail shorter (75–97 mm), but relatively long (140–160% of HB); mid-dorsal stripe from shoulders to base of tail.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the montane forest on the SSW slopes of Mt Kahuzi, east of L. Kivu, DR Congo.

Habitat The only known habitat is a small deep valley, with a small stream in the bottom, covered with dense montane forest and bamboo *Arundinaria alpina* (Dieterlen 1969a). Other common plants include the trees *Polyscias fulva*, *Symphonia globulifera* and *Neobutonia macrocalyx*, and the ferns *Cyathea manniana* and *Marattia fraxinea*. The only species of *Dendromus* living in montane forest.

Adaptations The structure of the forefoot and hindfoot, and the long tail, suggest that these mice are good climbers, and probably spend most their time above the ground (as do species of *Dendromus* that live in grasslands). The two known specimens were caught in traps on the ground, so it seems that they sometimes descend to the ground, perhaps when foraging.

Foraging and Food One stomach contained homogeneous well-chewed vegetable material, probably composed of seeds and fruits; green vegetation and animal remains were not present.

Conservation IUCN Category: Critically Endangered.

The very small known geographic range, and presumably low population numbers, are cause for concern. Schlitter (1989) classified the species as ‘Rare’.

Dendromus lovati LOVAT’S AFRICAN CLIMBING MOUSE

Fr. Souris arboricole de Lovat (Souris arboricole des plateaux éthiopiens); Ger. Lovats Klettermaus

Dendromus lovati (de Winton, 1900). Proc. Zool. Soc. Lond. 1899: 986. (publ. 1900). Menagesha, Ethiopia. 2800 m.

Taxonomy Originally described in the genus *Dendromys*. A very distinctive species, sometimes placed in a subgenus *Chortomys* by itself. Synonyms: none. Chromosome number: 2n = 44 (Lavrenchenko *et al.* 1997).

Description Distinctive very small dendromurine, with three very obvious stripes over the rump (quite unlike any other species of *Dendromus*). Pelage dense and soft. Dorsal pelage warm greyish-brown, sometimes with a slight russet tinge; hairs dark grey at base, brown or buff at tip; some longer hairs with black tips. Three black longitudinal stripes on back, each widening anteriorly and highlighted by paler sandy edges; middle stripe (ca. 40–50 mm long, 8 mm wide on mid-back, tapering to 0–2 mm at base of tail) extends from neck to rump; two outer stripes (ca. 25–30 mm long, 5–6 mm on mid-back tapering to 0–2 mm at base of tail) extend from chest to rump. Middle stripe may be partially split lengthwise into a double median stripe. Ventral pelage greyish; hairs grey at base, off-white at tip. Head similar in colour to back with small longitudinal black stripe from back of head to between eyes. Ears sparsely furred, sandy, with patch of black hairs on lower part of inner surface and on anterior part of outer surface. Whitish subauricular spot. Fore- and hindfeet sandy-brown. Hindfoot with five digits; Digit 1 short with

Dendromus lovati

nail, Digit 5 with nail-like claw. Tail long (ca. 100% of HB) with short hairs, dark above, paler below; comparatively short for a species of *Dendromus*. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species No other species of *Dendromus* has three longitudinal stripes on the back.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Confined to the high plateaux of Ethiopia, from 2500 to 3900 m. Known from only about nine locations (Yalden *et al.* 1976, Yalden & Largen 1992, Sillero-Zubiri *et al.* 1995b).

Habitat Typically found in highland grasslands, but extending into the dry *Heliochrysum* heathland at 3900 m on Tullu Deemtu, Bale (Sillero-Zubiri *et al.* 1995a).

Abundance Uncommon, known only from about 30 specimens (Yalden *et al.* 1976, Yalden & Largen 1992). Recent collecting in Ethiopia (1968–98, $n = \text{ca. } 6300$ rodents) yielded only 23 individuals of this species (Müller 1977, Rupp 1980, Yalden 1988, Sillero-Zubiri *et al.* 1995a, Afework Bekele 1996a, Lavrenchenko *et al.* 1997, Nievergelt *et al.* 1998).

Adaptations Nocturnal and terrestrial. Compared with other *Dendromus*, this short-tailed species appears to have no climbing ability. Several specimens have been caught at night in open grassland, where they moved ‘in short hops’ (collector’s notes: R. E. Cheesman, BMNH). Individuals show no obvious adaptations to living in harsh high-altitude environments, leading Sillero-Zubiri *et al.* (1995a) to speculate that they might hibernate during the dry season (when, under clear skies, it is extremely cold at night). However, captures have been made throughout the year (author’s records, collectors’ notes).

Foraging and Food Unknown, but probably granivorous.

Social and Reproductive Behaviour Little known. Appears solitary, one individual was ‘dug out from nest in tuft of grass’ (collector’s notes: R. E. Drake-Brockman, BMNH)) and another was found in a nest beneath a boulder.

Reproduction and Population Structure A juvenile ♂ trapped in Dec and a parous ♀ in Jan in Bale, and a juvenile caught in Mar (label, BMNH), suggest that reproduction occurs in the dry season.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

The highland grassland (woina dega) habitat is threatened by continuing modification and destruction by humans and their livestock.

Dendromus melanotis GREY AFRICAN CLIMBING MOUSE

Fr. Souris arboricole gris; Ger. Graue Klettermaus

Dendromus melanotis, Smith 1834. S. Afr. Quart. J. 2: 158. Near ‘Port Natal’ (= Durban), South Africa.

Taxonomy The taxonomic status of this species is uncertain, as manifested by karyotypic variability within the species and by the numerous synonyms currently recognized. The form *leucostomus* (known only from the type locality in Angola) is maintained as a synonym as in Musser & Carleton (1993) but raised to species status by Musser & Carleton (2005), following Hill & Carter (1941). Crawford-Cabral (1998) recorded that the dorsal pelage of *leucostomus* does not have a mid-dorsal stripe (cf. typical *D. melanotis*). Here, pending full taxonomic revision, *leucostomus* is retained as a synonym of *D. melanotis*. Synonyms: *arenarius*, *basuticus*, *capensis*, *chiversi*, *concinus*, *exoneratus*, *insignis* (Shortridge & Carter, 1938, not of Thomas, 1903), *leucostomus*, *nigrifrons*, *pallidus*, *pecilei*, *pretoriae*, *shortridgei*, *spectabilis*, *subtilis*, *thorntoni*, *vulturinus*. Subspecies: none. Chromosome number: $2n = 36$ (Matthey in Robbins & Baker 1978); $2n = 52$ (Dippenaar *et al.* 1983).

Description Very small slender mouse with soft woolly pelage and long slender tail. Dorsal pelage medium brown to rufous-brown, sometimes flecked with ashy-grey; hairs grey on basal two-thirds, pale brown on terminal third, some hairs with black tip. Dark stripe (usually 3–4 mm in width) extends along mid-dorsal line from between shoulders to base of tail. Ventral pelage white to greyish-white; hairs grey at base, off-white to pale grey at tip. Head with pointed muzzle and long vibrissae. Ears small and rounded, dark. Small white patch at base of ears. Limbs short. Forefeet with three long functional digits, Digits 1 and 5 greatly reduced but not absent. Hindfoot with five digits; Digit 1 short with nail, Digit 5 with nail (see also *D. nyikae*). Tail long (ca. 120–130% of HB), brownish above, paler below, sparsely haired. Nipples: 2 + 2 = 8.

Geographic Variation Pelage colour varies slightly throughout range. In the form *nigrifrons* (from e.g. Namibia, Kenya, Zambia), the mid-dorsal stripe extends to the forehead although usually indistinct between the ears and on the neck.

Similar Species

D. mystacalis. Similar in size and proportions; pelage rufous-brown; tail 140–160% of HB.

D. nyikae. Larger, head and body usually well over 70 mm; tail relatively longer (130–160% of HB).

D. mesomelas. On average larger, head and body generally well over 70 mm; tail relatively longer (130–140% of HB).

Distribution Endemic to Africa. Recorded in many biotic zones: Zambezian Woodland BZ, extending marginally into parts of Highveld and South-West Cape BZs of South Africa; Afromontane–Afroalpine BZ of Ethiopia; and (?) Guinea Savanna BZ of West Africa. Ranges widely from S and E South Africa through Botswana, E Namibia (Matson & Blood 1994), Zimbabwe, S Mozambique, Zambia, Malawi and S Angola (Crawford-Cabral 1998). Isolated populations in W Uganda (Wilson 1995), Tanzania and Kenya. Status in Ethiopia uncertain; distribution poorly known, and records may represent *D. mystacalis* (Yalden *et al.* 1976). In West Africa recorded at scattered localities in Nigeria, Benin, Liberia and Guinea (Happold 1987).

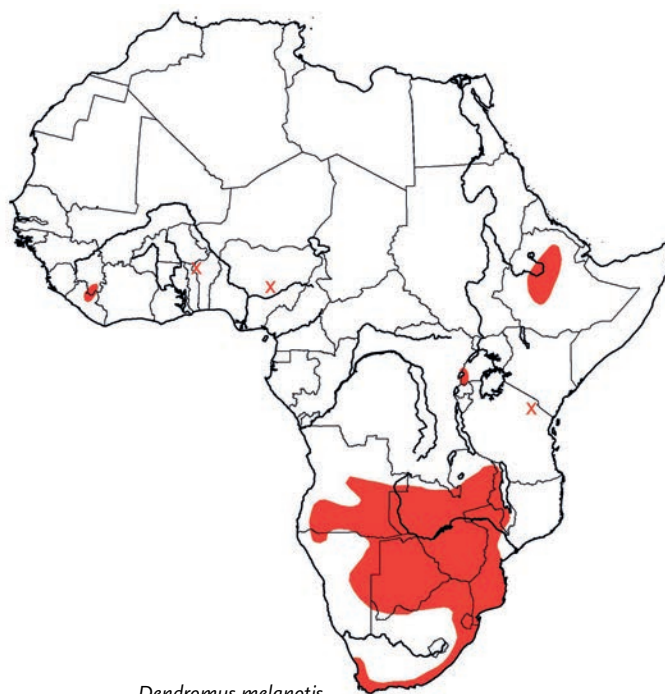

Habitat Inhabits a wide range of habitats. In southern Africa inhabits stands of tall *Hyparrhenia* grassland (Lynch 1994), short montane grassland (Rowe-Rowe & Meester 1982a, Taylor 1998), dry Kalahari scrub, fringes of rivers, dry *Baikiaea* woodland (Smithers 1971) and flood-plains (Sheppe & Haas 1981). May recolonize burnt grasslands within one month of fire (Rowe-Rowe & Meester 1981).

Abundance Relatively common. Third commonest species of small mammal in several different high-altitude grassland habitats in KwaZulu–Natal Province, South Africa (Rowe-Rowe & Meester 1982a). Detailed density estimates not available.

Adaptations Nocturnal. Limbs and tail modified for a semi-arboreal existence. Long, slender digits used to grip and climb thin stalks while long, prehensile tail provides balance. Weaves a grass nest with a single entrance, which is usually attached to grass stems or shrubs up to 1 m above the ground. Nest used only during the breeding season (Smithers 1971). May also use burrows up to 50 cm deep leading to a nest chamber with an emergency exit on the opposite side (De Graaff 1981).

Foraging and Food Predominantly granivorous. Frequency of occurrence of food types ($n = 14$ stomach contents) in sub-alpine grasslands of Drakensburg Mts, South Africa: seeds 100%, arthropods 24% and vegetable material 0% (Rowe-Rowe 1986).

Social and Reproductive Behaviour Poorly known. Thought to be predominantly solitary and territorial (Smithers 1971, Kingdon 1974). Known to fight ferociously with *D. mystacalis* in captivity. Parents reported to remain with offspring for some time after weaning.

Dendromus melanotis

Reproduction and Population Structure Little known. Breeding possibly confined to the wet season in southern Africa. Gravid ♀♀ with 2–8 embryos collected between Nov and Apr (Smithers 1971, Lynch 1994). In South Africa, juveniles captured at the end of the wet season during Apr and May (Rowe-Rowe & Meester 1982b).

Predators, Parasites and Diseases *Dendromus* spp. are difficult to distinguish in raptor pellets (Coetzee 1972), but remains have been found in the pellets of Barn Owls *Tyto alba* (Vernon 1972) and Black-shouldered Kites *Elanus caeruleus* (Mendelsohn 1982).

Conservation IUCN Category: Least Concern.

Dendromus mesomelas BRANTS'S AFRICAN CLIMBING MOUSE

Fr. Souris arboricole noisette; Ger. Brants Klettermaus

Dendromus mesomelas (Brants, 1827). Het. Geslacht der Muizen, p. 122. Sunday's River, South Africa.

Taxonomy Originally described in the genus *Dendromys*. The name *mesomelas* refers to the large *Dendromus* of southern and central Africa (Musser & Carleton 1993) in which Digit 5 of the forefoot is absent. Some names formally included in *D. mesomelas* (see Misonne 1974) are now regarded as valid species (i.e. *D. insignis*, *D. nyasae*, *D. oreas* and *D. vernayi*). Synonyms: *ayres*, *major*, *pumilio*, *typicus*, *typus*. Subspecies: none. Chromosome number: not known.

Description Very small slender mouse with soft woolly pelage and very long slender tail. Dorsal pelage rufous-brown; hairs dark grey, rufous-brown to gingery-brown terminally. Dark mid-dorsal stripe of variable intensity from shoulders to base of tail; absent in some individuals. Ventral pelage off-white; hairs dark at base with whitish tip. Head with pointed nose and long vibrissae. Ears small and rounded. Limbs short. Forefeet with three long functional digits, Digit 1 greatly reduced and Digit 5 absent. Hindfoot with five digits; Digit 1 short with nail, Digit 5 long and opposable with claw. Tail very long (ca. 130–140% of HB), brownish above, paler below and sparsely haired. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

D. mystacalis. Smaller, HB less than 65 mm; ventral pelage white, hairs with white base. Tail 140–160% of HB.

D. nyikae. Dorsal pelage pale to dark cinnamon suffused with grey; ventral pelage white, hairs with white base. Tail long (130–160% of HB).

D. melanotis. Smaller, HB usually less than 70 mm; dorsal pelage ashy-grey; ventral pelage greyish-white. Tail 120–130% of HB.

Distribution Endemic to Africa. Zambezian Woodland BZ, extending to southern part of Somalia–Masai Bushland BZ and to Coastal Forest Mosaic BZ (in South Africa). Distribution disjunct. Recorded in S and E South Africa, W Swaziland, N Botswana, Namibia (Caprivi Strip), Mozambique (Gorongosa Mt) (De Graaff 1981), NE and NW Zambia (Ansell 1978), S and N Malawi (Ansell & Dowsett 1988), SE DR Congo (Musser & Carleton 1993) and C Tanzania (Swynnerton & Hayman 1950).

Habitat Inhabits a wide range of grassland habitats mostly in temperate environments. In southern Africa also inhabits swamps and damp grasslands (Hanney 1965, Taylor 1998) as well as afromontane forest (Rowe-Rowe & Meester 1982, Monadjem 1998a). Prefers wet moist habitats and is absent from hot, low-lying river basins, arid savannas and miombo woodland.

Abundance Relatively common. No density estimates available, but relatively numerous in leaf-litter of afromontane forest in Swaziland (A. Monadjem unpubl.).

*Dendromus mesomelas*

Adaptations Mostly nocturnal, but may also be active during the day. Limbs and tail modified for a semi-arboreal existence. Long, slender digits used to grip and climb thin stalks while long, prehensile tail provides balance. Weaves a grass nest, which may be placed either above or below ground (Kingdon 1974). Also occupies nests of birds, e.g. *Ploceus* spp. (De Graaff 1981). Believed to be more terrestrial than other members of the genus (see also *D. lovati*).

Foraging and Food Predominantly granivorous. Proportional contribution of food types in stomach contents: 12% vegetable material, 87% seeds, 1% arthropods (n = 5, Swaziland; Monadjem 1997b). Elsewhere, in Botswana and South Africa, insects contribute a greater proportion of the diet (Smithers 1971, Rowe-Rowe 1986). Seasonal availability may limit the consumption of insects to the wet season.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Reproduction possibly confined to the wet season in southern Africa, but gravid ♀♀ have been collected in the dry season in Malawi (Hanney 1965). Embryo number: 2–6 (Hanney 1965, Taylor 1998).

Predators, Parasites and Diseases *Dendromus* spp. are difficult to distinguish in raptor pellets (Coetzee 1972), but remains have been found in the pellets of Barn Owls *Tyto alba* (Vernon 1972) and Black-shouldered Kites *Elanus caeruleus* (Mendelsohn 1982). Ectoparasites include the fleas *Ctenophthalmus verutus*, *C. cophurus*,

Dinopsyllus grypurus and *Nosopsyllus incisus*. May be susceptible to plague (De Graaff 1981).

Conservation IUCN Category: Least Concern.

Dendromus messorius BANANA AFRICAN CLIMBING MOUSE

Fr. Souris arboricole de bananier; Ger. Bananen-Klettermaus

Dendromus messorius (Thomas, 1903). Ann. Mag. Nat. Hist., ser. 7, 12: 340. Efulen, Cameroon.

Taxonomy Originally described in the genus *Dendromys*. Considered to be a synonym or subspecies of *D. mystacalis* (Rosevear 1969, Misonne 1974, Delany 1975 [referring to *ruddi*]) or as a valid species (Hatt 1940a, Verheyen & Verschuren 1966, Dieterlen 1971, Musser & Carleton 1993, 2005). Synonyms: *haymani*, *kumasi*, *ruddi*. Subspecies: none. Chromosome number: not known.

Description Very small slender climbing mouse with long tail and without mid-dorsal stripe. Dorsal pelage gingery-brown; hairs dark grey on basal three-quarters, gingery-brown on terminal one-quarter. Usually without mid-dorsal stripe (cf. some other *Dendromus* spp.); occasionally very faint brownish stripe is visible. Flanks paler than back. Ventral pelage pure white; clearly delineated from colour of flanks. Head similar colour to dorsal pelage. Ears comparatively large covered with short ginger hairs. Upper lips, lower lips, cheeks, throat and chest whitish. Long stiff black vibrissae on muzzle. Fore- and hindlimbs whitish. Forefoot with three functional digits (Digits 2, 3 and 4). Hindfoot with five digits; Digit 1 short with nail (or absent), Digit 5 long and opposable with claw. Tail very long (ca. 140% of HB), dark, with short blackish bristles. Skull: upper incisors opisthodont. Nipples: 2 + 2 = 8.

Geographic Variation Some individuals have a faint brownish stripe (e.g. *kumasi* from Ghana [Rosevear 1969]).

Similar Species

D. mystacalis. Similar size; well-developed dark mid-dorsal stripe; ventral pelage whitish; partially parapatric.

D. mesomelas. Larger; well-developed dark mid-dorsal stripe; ventral pelage off-white, hairs dark at base with whitish tip; partially parapatric.

Distribution Endemic to Africa. Rainforest BZ and Northern and Eastern Rainforest–Savanna Mosaics. Also Afroalpine BZ in Uganda and E DR Congo. Recorded from Ghana, Togo, Benin, E Nigeria (Umuahia only), Cameroon, DR Congo and Uganda. Distribution disjunct. Limits uncertain; may also occur in S

Dendromus messorius

Sudan and W Kenya (Musser & Carleton 2005). Recorded at 2000–3000 m on Mt Elgon (Clausnitzer & Kityo 2001, as *D. mystacalis ruddi*; see Musser & Carleton 2005).

Habitat Preferred habitat is banana plants in farmlands. Also found among sweet potatoes (Hatt 1940a), in holes in trees, in fissures, cracks and trunks of trees in gallery forest, and orange trees (Verheyen & Verschuren 1966). In Cameroon, recorded in long grass (Rosevear 1969).

Abundance May be common in some localities; in Garamba N. P., NE DR Congo, commoner than sympatric *Dendromus mesomelas* and *D. mystacalis* (Verheyen & Verschuren 1966).

Adaptations Nocturnal. At Medje, NE DR Congo, the nest of a ♀ with three young was ‘inserted between the bases of banana leaves, close to the stem, about eight feet from the ground. The nest was hardly visible being well concealed between the large bases of the closely growing banana leaves. Sliced up banana leaves were the only material used outside. On the underside larger pieces were utilised, but inside the leaves were so finely split that the material looked like fine grass’ (H. Lang in Hatt 1940a). This nest was about the size of a man’s fist, roundish in shape, with a single entrance. Two other nests, each occupied by a single ♂, were similar in construction. Nests also built in long grass, and a bush (type specimen) (Cameroon; Rosevear 1969).

Foraging and Food Vegetable material present in two stomachs (Hatt 1940a). Also feeds on fruits of *Sarcocephalus esculentus* (Verheyen & Verschuren 1966).

Social and Reproductive Behaviour Assumed to be solitary. The nests referred to above each occupied by a single adult animal.

Reproduction and Population Structure No information.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern. In Uganda, conserved in four National Parks (Mgahinga N. P., Bwindi Impenetrable N. P., Rwenzori N. P. and Semliki N. P. [Wilson 1995]).

D. C. D. Happold

Dendromus mystacalis CHESTNUT AFRICAN CLIMBING MOUSE

Fr. Souris arboricole de Heuglin; Ger. Kastanienbraune Klettermaus

Dendromus mystacalis Heuglin, 1863. Nova Acta Acad. Caes. Leop.-Carol., Halle 30: 2, suppl. 5. Baeschlo region, Ethiopia.

Taxonomy A smaller version of *D. mesomelas* of southern Africa. Probably closely related to *D. mesomelas*, the two species forming a species-pair (Avery 1998; see also Musser & Carleton 2005). Synonyms: *acraeus*, *ansorgei*, *capitis*, *jamesoni*, *nairobae*, *ochropus*, *pallascens*, *pongolensis*, *uthmoelleri*, *whytei*. Subspecies: none. Chromosome number: 2n = 38 (Matthey in Robbins & Baker 1978).

Description Very small slender mouse with soft woolly pelage and very long slender tail. Dorsal pelage bright rufous-brown. Dark stripe on mid-dorsal line from shoulders to base of tail. Ventral pelage whitish, ventral hairs with white base. Head with pointed nose and long vibrissae. Ears small and rounded. Limbs short. Forefeet with three long functional digits, Digit 1 greatly reduced, Digit 5 absent. Hindfoot with five digits; Digit 1 short with nail, Digit 5 long and opposable with claw. Tail very long (ca. 140–160% of HB), brownish above, paler below, sparsely haired. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

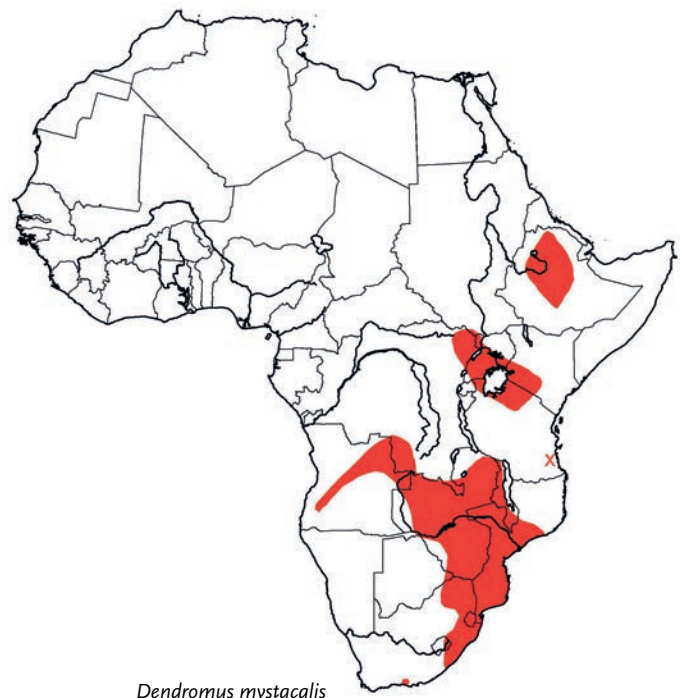

Similar Species

D. melanotis. On average larger; dorsal pelage ashy-grey; tail 140–160% of HB.

D. nyikae. On average larger; dorsal pelage pale to dark cinnamon; tail 130–160% of HB.

D. mesomelas. Larger; black mid-dorsal stripe sometimes absent; ventral hairs with dark base; tail 130–140% of HB.

D. messorius. Dorsal stripe absent. West Africa and central Africa only.

Dendromus mystacalis

Distribution Endemic to Africa. Zambezian Woodland BZ and parts of Eastern Rainforest–Savanna Mosaic and Afromontane–Afroalpine BZ in eastern Africa. Occurs widely from E South Africa northwards through Zimbabwe, Mozambique and Zambia. Ranges westwards in N Botswana and Angola. Isolated populations in E DR

Congo, Uganda, S Sudan, N Tanzania and S Kenya, and Ethiopia (Yalden *et al.* 1976).

Habitat Occupies a wide range of savanna habitats; presence of dense grass cover is essential. In Swaziland, high vegetation density in first 10 cm above ground appears to be a critical habitat feature (Monadjem 1997a). Tall stands of *Hyperthelia-Hyparrhenia* grassland are favoured, but also occurs in rank vegetation fringing wetlands, drainage lines and afro-montane forests. Predominantly a low-altitude species occurring below 2000 m (1200 m in southern Africa) generally preferring drier conditions than *D. nyasae (kivu)* (Dieterlen 1971). In Swaziland, associated with hilly landscapes (Monadjem 1999a).

Abundance Relatively common to abundant. Population densities not easy to determine because individuals do not regularly enter rodent traps. Densities of up to 19.8/ha reported from DR Congo (Misonne 1963) and 2.5/ha from Swaziland (A. Monadjem unpubl.).

Adaptations Nocturnal. Limbs and tail modified for a semi-arboreal existence. Long, slender digits used to grip and climb thin stalks while long, prehensile tail provides balance. Weaves a grass nest with multiple entrances, in which offspring are raised. Adults also use nest for resting. Nest usually located in tall grass about 1 m above ground (Monadjem 1998a) but may also be located higher up in gardens (Kingdon 1974). Known to utilize burrows and disused nests of weaver birds.

Foraging and Food Omnivorous. Diet (assessed by stomach contents): 44% vegetable material, 40% seeds, 16% arthropods (n = 6, Swaziland; Monadjem 1997b). Forages both on the ground and on tall, dense grass.

Social and Reproductive Behaviour In Swaziland, pairs were regularly trapped together in same rodent live-trap, suggesting that individuals often forage in pairs. Known to fight ferociously with *D. melanotis* in captivity.

Reproduction and Population Structure Breeding confined to the wet season with juvenile recruitment mostly Jan–Mar (Zimbabwe; Smithers & Wilson 1979). Embryo number: usually 3–4, but up to eight (Rautenbach 1982). In Swaziland, number of individuals trapped fluctuated seasonally; highest numbers in dry season between Jun–Oct (Monadjem & Perrin 2003). ‘Disappearance’ of these mice in the wet season was attributed to a change in foraging tactics rather than population fluctuations. In southern Africa, most grasses set seed in the late wet season, at which time individuals of this species probably take seeds from the grass stalks, rather than from the ground.

Predators, Parasites and Diseases *Dendromus* spp. are difficult to distinguish in raptor pellets (Coetzee 1972), but remains have been found in the pellets of Barn Owls *Tyto alba* (Vernon 1972) and Black-shouldered Kites *Elanus caeruleus* (Mendelsohn 1982).

Conservation IUCN Category: Least Concern.

Dendromus nyasae (kivu) KIVU AFRICAN CLIMBING MOUSE

Fr. Souris arboricole du Kivu.; Ger. Kivu-Klettermaus

Dendromus nyasae Thomas, 1916. Ann. Mag. Nat. Hist., ser. 8, 18: 241. Nyika Plateau, Malawi.

Dendromus kivu Thomas, 1916. Ann. Mag. Nat. Hist., ser. 8, 18: 242. Buhamba, Kivu region, DR Congo.

Taxonomy Thomas (1916b) described *kivu* as a subspecies of *D. insignis* and hence a member of the *mesomelas* species group, where it was also placed by Bohmann (1942). Musser & Carleton (1993) considered *kivu* to be a distinct species, morphologically similar to *D. mesomelas*. Referring to Osgood's (1936) two samples of *Dendromus* from Rwenzori, Musser & Carleton (1993) identified them as *D. lunaris* and *D. insignis*. *Dendromus lunaris* was found to be identical with (the pre-dated) *D. kivu*. The same sympatric combination – *D. kivu* and *D. insignis* – were found in two other series from the Kivu region. Dieterlen (1971, 1976a) recorded three species living sympatrically

in the region west of L. Kivu, and named them as *D. mesomelas kivu* (now *D. insignis*), *D. melanotis* (now *D. kivu*) and *D. mystacalis*. Musser & Carleton (2005) included *kivu* as a synonym of *nyasae*. This profile refers to what the present author considers as *D. kivu* from the Kivu region. The relationship between *kivu* and *nyasae* requires further investigation. Morphologically, *D. nyasae* seems to be most closely related to *D. vernayi* from Angola, *D. oreas* from the mountains of E Cameroon, and *D. insignis* from the mountains of East Africa (Musser & Carleton 2005). Synonyms: *hintoni*, *kivu*, *lunaris*. Subspecies: none. Chromosome number: not known.

Description Small climbing mouse (although one of the largest species of *Dendromus*) with a long mid-dorsal stripe and a long tail. Pelage colouration varies with age (see below). Adult dorsal pelage typically rich brown, tending to be darker on anterior part of body; hairs ash-grey at base, brown at tips. Pelage may appear greyish-brown when basal hair colour visible on surface. Dorsal stripe black, 2–3 mm wide from ca. 2 cm behind head to base of tail. Flanks yellowish-brown. Ventral pelage silvery-white; hairs grey at base, silvery-white at tip. Chin and throat with pure white patches. Eyes relatively large. Hindfoot with short hair, silver-grey, rarely with reddish tinge. Hindfoot with five digits; Digit 1 short, Digit 5 long and opposable with short claw. Tail very long (ca. 124% of HB), colour and hairiness very variable. Ventral pelage in young and subadults (when several weeks or months in age) may be whitish or greyish. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

- D. insignis*. HB on average slightly larger; tail slightly longer (mean 97 mm) but of similar relative length; mid-dorsal stripe broader (ca. 4 mm) from back of head to base of tail.
- D. mystacalis*. HB smaller; tail on average shorter (mean 84.8, 90.4 mm) but relatively longer (ca. 140–160% of HB); mid-dorsal stripe from shoulders to base of tail.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from the western and eastern slopes of the Rwenzori Mts and the Kivu region of E DR Congo, from 1300–4200 m (see below). May be considered as an ‘Albertine Rift Valley’ endemic. Other East African montane forms, similar or identical to *D. kivu*, are known from Tanzania, Rwanda, Kenya, but their taxonomic status is uncertain. Musser & Carleton (2005) give the distribution (as *D. nyasae*) as follows: Western Rift Mts and Rwenzori Mts (E DR Congo, W Uganda), south

through E DR Congo to the Marungu Mts in SE DR Congo, Mbizi Mts in W Tanzania, Rungwe and Ukinga in SW Tanzania, Nyika Plateau in NE Zambia and N Malawi, and highlands in S Malawi; also through the Eastern Arc Mts in E Tanzania (Uzungwa Mts, Uluguru highlands, Ukaguru Mts, Nguru Mts and South Pare Mts).

Habitat Occurs over a wide range of habitats along the Albertine Rift Valley, and at altitudes of 1300–4200 m on the Rwenzori Mts (Verschuren *et al.* 1983) and 1600–2400 m to the west of L. Kivu (Dieterlen 1971, 1976a). All habitats are characterized by moist dense vegetation suitable for climbing. Favoured moist habitats at lower altitudes include grassy vegetation between cultivated fields, banana plantations and the edges of swamps. Above 2000 m occurs in sparse tree and/or bamboo forests and on the edges of swamps. At 4200 m (L. Marion, Rwenzori Mts), found in the afroalpine vegetation between immortelles (strawflowers) and alchemillas (Dieterlen 1976a, Verschuren *et al.* 1983).

Abundance In favoured habitats, e.g. at the edge of grassy thickets, populations may be abundant and comprise up to 10% of individuals in a community of 10–15 small mammal species (Dieterlen 1967a, b, 1971).

Adaptations Mostly nocturnal and arboreal. Agile climbers well adapted for life on stems and twigs. The large opposable Digit 5 of the hindfeet and the long semi-prehensile tail are used for holding onto small narrow stems. Ball-shaped nests, made of grass and leaves, are fastened between stalks and twigs some 30–80 cm above the ground (Dieterlen 1971).

Foraging and Food Omnivorous or insectivorous. Five stomachs contained a mixture of seeds and the remains of insects, and two other stomachs contained only insects (Dieterlen 1971, 1976a).

Social and Reproductive Behaviour No information, but it is presumed that individuals are mostly or entirely solitary.

Reproduction and Population Structure Near L. Kivu, reproduction occurs throughout most of the year. Most births have been recorded during the wet season (Sep–May) with a peak of reproductive activity in Jan–Mar (73% of the ♀♀ active, $n = 15$). In the dry season, only one (11%) out of nine ♀♀ was reproductively active (Dieterlen 1971). Gestation: probably 23–27 days. Mean litter-size: 4. Young are altricial at birth, unable to crawl, and the eyes and ears are closed. First hairs visible and dorsal stripe showing as pigmented skin Day 11. Incisors erupt Day 11. Molar teeth erupt Day 15–20. Eyes open, walking and climbing begins Day 22–24. Dark juvenile pelage complete (young much darker than adults) Day 24. Weaning begins Day 24. Young totally weaned and appearance like small adults (although HB not yet adult size) Day 35. Sex ratio: 69% : 31% (ca. 7 : 3; $n = 83$; Dieterlen 1967a, b, 1971; see also *D. insignis*).

Predators, Parasites and Diseases Small carnivores, birds and snakes are potential predators. The small intestine of one adult contained many parasitic worms, some 50 mm long.

Conservation IUCN Category: Least Concern.

Dendromus nyikae NYIKA AFRICAN CLIMBING MOUSE

Fr. Souris arboricole de Nyika; Ger. Nyika-Klettermaus

Dendromus nyikae Wroughton, 1909. Ann. Mag. Nat. Hist., ser. 8, 3: 248. Nyika Plateau, Malawi.

Taxonomy Closely related to *D. melanotis*. Sometimes placed (with *D. melanotis*) in the subgenus *Poemys*, which is characterized by the flattened nail on the Digit 5 of hindfoot (Crawford-Cabral 1998). *Dendromus nyikae angolensis* is considered to be a synonym of *D. pecilei* in Angola by Crawford-Cabral (1998) but *pecilei* is treated as a synonym of *D. melanotis* by Musser & Carleton (2005). Synonyms: *angolensis*, *bernardi*, *longicaudatus*. Subspecies: none. Chromosome number: not known.

Description A very small climbing mouse with a mid-dorsal thin black stripe, and very long tail. Dorsal pelage pale to dark cinnamon suffused with grey. Dorsal hairs short (6–7 mm), soft and dense; grey at base, cinnamon at tip. Black mid-dorsal stripe from shoulders to base of tail, sometimes rather inconspicuous and irregular; hairs of stripe grey with dark cinnamon or black tip. Ventral pelage usually pure creamy-white; hairs in some individuals medium grey at base, with small white tip. Throat and chest yellow or rufous in some individuals (?♂♂; ?glandular secretions). Head cinnamon, without black patch on crown. Small white subauricular patch. Ears rounded, conspicuous (standing out from side of head), brown with short brown hairs. Hindfoot with five digits; Digit 1 short with nail, Digit 5 very long and opposable with nail (see also *D. melanotis*). Tail long (ca. 130–160% HB), scaly with small pale bristles; longer hairs at tip. Nipples: not known.

Geographic Variation None recorded.

Similar Species

D. melanotis. Similar in size; well-defined wide dorsal stripe; flat nail on Digit 5 of hindfoot.

D. mystacalis. On average smaller; black dorsal stripe; ventral pelage pure white; small claw on Digit 5 of hindfoot.

D. mesomelas. On average larger HB, T and HF; dorsal stripe dark but variable; small claw on Digit 5 of hindfoot.

Distribution Endemic to Africa. Zambezian Woodland and Afromontane–Afroalpine BZs. Recorded from Angola, S DR Congo, Zambia, Zimbabwe, Malawi, SW Tanzania, Mozambique and N South Africa. A specimen of *D. melanotis nyikae* from Ukerewe I. in L. Victoria is, in fact, *D. mystacalis* (Musser & Carleton 2005).

Dendromus nyikae

Habitat Long grass in grassland savannas and plateaux, mostly at higher altitudes. May occur in grassland habitats within pine plantations. On Nyika Plateau, Malawi, some individuals found in unoccupied standard beehives (specimens; HZM). Does not enter forested habitats except very rarely.

Abundance Rather uncommon, although may be locally abundant. In Malawi, 'widespread but probably limited to upland areas' (Ansell & Dowsett 1988). Comprised 9.2% of grassland small rodents during a mark-capture study (n = 215) on Zomba Plateau, Malawi (1800 m) (Happold & Happold 1989c), but not present in tall *Hyparrhenia* and *Panicum* grasslands in Liwonde N. P., Malawi (500 m) (Happold & Happold 1990). In Malawi, numbers were highest where the montane grasslands were tall (i.e. 40–80 cm, depending on time of year and location), and lowest (or absent) where grasslands were short and after burning (Happold & Happold 1989c).

Adaptations Nyika Climbing Mice are adapted for climbing on thin tall grass stems. Their small size and grasping feet allow them to climb up and down grass stems from the flowerheads to ground level. When climbing, the hindfeet are held almost at right angles to the body. A grass stem is grasped by the forefeet as would a human hand, and the flexible Digits 1 and 5 of the hindfeet encircle the stem. The tail is stretched out from the rump at various angles to provide balance, or the tip is wound several times around a stem to provide an extra holding point. Locomotion is by swiftly climbing up and down stems, and reaching across gaps (equivalent to at least the length of head and body) to adjacent stems (D. C. D. Happold unpubl.). The burrow is a simple tunnel in the soil with a nest chamber lined with dead leaves (Hanney 1965).

Foraging and Food Seed-heads of grasses are obtained by climbing to the top of a stem, biting through part of the stem below the seed-head so that the head falls over but is still attached, and then nibbling at the seeds (D. C. D. Happold pers. obs.). Analysis of stomach contents (n = 6) revealed five with white vegetable material, one with grain husks and three with insects, including beetles (Hanney 1965).

Social and Reproductive Behaviour No information. Nyika Climbing Mice make a high-pitched squeal when disturbed.

Reproduction and Population Structure Pregnant ♀ in Nov (Malawi; Hanney 1965); lactating ♀ in Aug (S Tanzania; Kingdon 1974). Embryos: 4 (n = 1, Hanney 1965).

Predators, Parasites and Diseases Comprised 6% (n = 100 prey) and 30% (n = 46 prey) of prey numbers in the pellets of African Grass-owls *Tyto capensis* on Zomba Plateau, Malawi. When foraging on the tops of grass stems, they are probably easy prey for owls. Because of their small size, climbing mice comprised only 1% and 6% of prey biomass (Happold & Happold 1986).

Conservation IUCN Category: Least Concern.

D. C. D. Happold

Dendromus oreas CAMEROON AFRICAN CLIMBING MOUSE

Fr. Souris arboricole du Cameroon; Ger. Kamerun-Klettermaus

Dendromus oreas Osgood, 1936. Field Mus. Nat. Hist., Zool. Ser. 20: 236.

South-west side of Mount Cameroon, Nigeria (now in Cameroon). 9000 ft (2740 m).

Taxonomy Described as a distinct species, but subsequently considered to be a synonym of *D. mesomelas* (Bohmann 1942, Rosevear 1969, Misonne 1974). Referred to as *D. mesomelas oreas* by Rosevear (1969). Musser & Carleton (1993, 2005) reinstated *oreas* as a valid species, and considered it to be related to *Dendromus lunaris* (now *D. nysae [kivu]*), and not to be a geographic outlier of *D. insignis*. Synonyms: none. Chromosome number: not known.

Description Very small climbing mouse with an indistinct mid-dorsal stripe and long tail. Dorsal pelage medium brown. Black mid-dorsal stripe from mid-back to base of tail, often rather indistinct. Ventral pelage varied, from dark rufous to pale greyish-yellow; hairs dark at base. White or cream patches on chin and throat, and around anus. Ears blackish-brown, with fine covering of blackish-tawny hairs; pale spot at base of outer margin of each ear, sometimes indistinct. Hindfoot with five digits; Digit 5 long and opposable with claw. Tail very long (ca. 135% of HB), dusky above, paler below. Nipples: not known.

Geographic Variation None recorded.

Similar Species

D. messorius. On average smaller; mid-dorsal stripe absent; usually occurs at lower altitudes; recorded from Cameroon (and many other countries) but not from mountainous habitats (see below).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ; known only from Mt Cameroon (1700–4000 m), Mt Manenguba (1800–1900 m, ca. 120 km NE of Mt Cameroon) and Mt Kupé (ca. 80 km NE of Mt Cameroon, 850 m) in Cameroon (Eisentraut 1963, Rosevear 1969). Probably endemic to the mountains of W Cameroon. This is the only known species of *Dendromus* on the mountains of Cameroon.

Habitat Montane savannas above the montane forest zone, from ca. 1675 m to ca. 2900 m, on the ground amongst boulders of lava (Mt Cameroon). Also recorded on dry grassy and scrubby slopes (Mt Manenguba), and in plantations and farmlands (Mt Kupé). Has not been recorded in montane forest habitats at lower altitudes on these mountains.

Adaptations Mostly terrestrial, diurnal and nocturnal. Although well adapted for climbing, these mice spend most of their life on the ground and in their subterranean burrows.

Reproduction One ♀ with five embryos in late Nov (Eisentraut 1963).

Conservation IUCN Category: Vulnerable.

Geographic range is very limited and populations on each of the mountains are isolated.

Dendromus vernayi VERNAY'S AFRICAN CLIMBING MOUSE

Fr. Souris arboricole de Vernay; Ger. Vernays Klettermaus

Dendromus vernayi Hill and Carter, 1937. Amer. Mus. Novit. 913: 4. Chitau, Angola. 4930 ft (1500 m).

Taxonomy Described as a subspecies of *Dendromus mesomelas* (see also Misonne 1974). *Dendromus vernayi* is morphologically distinct from *D. nyasae* and *D. oreas*, and is probably phylogenetically more closely related to these species than to any other species of *Dendromus* (Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Very small climbing mouse with dark mid-dorsal stripe. Pelage relatively long and silky. Dorsal pelage ochraceous and cinnamon-brown; hairs dark grey at base. Mid-dorsal stripe wide (ca. 4.5 mm). Ventral pelage varied, bright pinkish-buff or buffy-grey; hairs medium grey at base. Pure white patch on throat and in axillary region. Ears blackish on outer surface, short orange hairs on inner surface. Upper surface of fore- and hindfeet pinkish-buff. Hindfoot relatively long (>19 mm). (No information on digits of fore- and hindfoot.) Tail very long (ca. 130% of HB), dark above, paler below. Skull: rostrum heavier and shorter than in other species of *Dendromus*. Nipples: not known.

Geographic Variation None recorded.

Similar Species

D. melanotis. Body size slightly larger (mean HB: 68 mm); skull (GLS, GWS) slightly smaller; tail usually longer; hindfoot shorter (usually <19 mm); ventral pelage white to greyish-white; widespread distribution; probably sympatric.

D. mystacalis. Similar body size (although mean HB slightly smaller); ventral pelage white; tail usually longer (and relatively longer, 140–160% of HB); hindfoot on average shorter (usually <19 mm); ear smaller (mean 9.3 mm); M¹–M³ shorter; widespread distribution; probably sympatric.

D. nyikae. Body size on average slightly larger, but with shorter HF (mean 16.7 mm); ventral pelage creamy-white; tail on average longer and relatively longer (up to 160% of HB); widespread distribution; probably sympatric.

Distribution Endemic to Africa. Zambezan Woodland BZ. Known only from the type locality near Chitau (1500 m) in C Angola (Hill & Carter 1937, 1941, Crawford-Cabral 1998).

Habitat Not known.

Abundance Very rare. Known only from 14 specimens from the type locality.

Remarks No other ecological or biological information available. Three other species of *Dendromus* (*D. melanotis*, *D. mystacalis* and *D. nyikae*) also occur in C Angola.

Conservation IUCN Category: Data Deficient.

The geographic range is very small, and all known individuals are from a single population.

GENUS *Dendroprionomys* Velvet Climbing Mouse

Dendroprionomys F. Petter, 1966. Mammalia 30: 129. Type species: *Dendroprionomys rousseloti* F. Petter, 1966.

Dendroprionomys is a monotypic genus described in 1966 (Petter 1966b), and known only from Congo. The genus possesses a mixture of characters typical of the genera *Dendromus* and *Prionomys* (hence the name). The distinguishing characters of the genus are very small size, long tail relative to HB, feet modified for climbing, elongated Digit 1 of hindfoot (as in *Prionomys*) and opposable Digit 5 of hindfoot (as in *Dendromus*) (Figure 30). Skull characters include: upper incisors orthodont or slightly opisthodont, each with a longitudinal groove (as in *Dendromus*); elongated frontal-nasal region (cf. *Dendromus* and *Prionomys*); box-shaped braincase (as in *Prionomys*); crescent-shaped edges of inter-orbital constriction (as in *Prionomys*); anterior palatal foramina very short ending posteriorly at level of infraorbital foramen and far anterior to M¹ (as in *Prionomys*); and molar teeth

Dendroprionomys rousseloti.

Figure 31. Skull and mandible of *Dendroprionomys rousseloti* (MNHN 1967/1368, with additional information from Petter 1966b).

with tall pointed cusps, two rows on upper molars and one row on lower molars (similar to *Prionomys* but much more developed) (Figure 31). The single species is *Dendroprionomys rousseloti*.

D. C. D. Happold

Dendroprionomys rousseloti VELVET CLIMBING MOUSE (CONGO TREE MOUSE)

Fr. Souris arboricole de Brazzaville; Ger. Samt-Klettermaus

Dendroprionomys rousseloti Petter, 1966. Mammalia 30: 129. Brazzaville, Congo.

Taxonomy The single species in the genus was described by Petter (1966b) on the basis of three specimens. Initially placed in the Dendromuridae (Chaline *et al.* 1977), the species is now placed in Nesomyidae (subfamily Dendromurinae) (Musser & Carleton 2005). Phylogenetic analysis of its dental pattern suggested that *Dendroprionomys* is closely related to *Prionomys* (Denys *et al.* 1995). Synonyms: none. Chromosome number: not known.

Description Very small mouse with very long tail (similar to *Dendromus* spp.). Pelage dense, short and soft, rather fluffy. Dorsal pelage medium-brown, tinged with russet especially on flanks; hairs grey at base with brown tips. Ventral pelage greyish-white; hairs grey on basal half, white on terminal half. Head similar in colour to dorsal pelage, with conspicuous brownish-black stripe from muzzle to (and around) eyes. Lips, chin and throat white. Long well-developed vibrissae. Ears long, darkly pigmented, seemingly naked but sparsely covered with extremely short dark hairs. Limbs short, white. Forefeet with four digits: Digit 1 absent, Digits 2, 3 and 4 long with short claws, Digit 5 short with (or without) very small claw. Hindfeet with five digits: Digit 1 short and stumpy with very small claw; Digits 2, 3, 4 and 5 long with claws; Digit 5 opposable (Figure 30). Tail very long and thin (ca. 140% of HB), brown, with scales arranged in rings, very short black bristles. Skull with globular-shaped braincase and narrow rostrum region, upper incisor teeth orthodont or slightly opisthodont, each with single groove; anterior palatal foramina not reaching level of M¹; small molar teeth with tall pointed cusps not linked in transverse chevrons but linked by longitudinal stephanodont crests. See also genus profile. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Prionomys batesi. Pro-odont incisors without longitudinal groove; small ears; complete open longitudinal groove on upper molars; small Digit 5 of the hindfoot not opposable; Cameroon and Central African Republic.

Dendromus spp. Mid-dorsal stripe (in most species); Digit 1 on hindfoot very short; Digit 5 long and opposable.

Distribution Endemic to Africa. Rainforest BZ. Recorded only from the type locality in the Zoological Gardens at Brazzaville, SE Congo.

Habitat The Zoological Garden at Brazzaville is situated on a sand forest.

Dendroprionomys rousseloti

Abundance Extremely rare. Known from only eight specimens from the same locality, seven collected in 1948 and one in 1966.

Remarks The characters of the feet suggest an ability to climb on stems of grasses and herbs, and the long tail suggests that (like *Dendromus* spp.) it may be prehensile. The structure of the molar teeth suggest a partly insectivorous diet. The two lines of tall cusps on the lower molars fit into the grooves between the two lines of tall cusps on the upper molars (Petter 1966b), but to a lesser extent than in *Prionomys*.

Conservation IUCN Category: Data Deficient. Considered as 'Rare' by Schlitter (1989).

The very small geographic range and presumed rarity are cause for concern.

GENUS *Malacothrix*

Long-eared Mouse

Malacothrix Wagner, 1843. In: Schreber, Die Säugethiere, Suppl. 3: 496. Type species: *Otomys typicus* A. Smith, 1834.:

Malacothrix typica.

A monotypic genus occurring only in semi-arid habitats of southern Africa. Morphologically very distinctive compared with species of *Dendromus*, *Megadendromus* and *Steatomys* (Denys *et al.* 1995). The cheekteeth are small and delicate, similar to those of *Dendromus* and *Steatomys* spp., and extend far forward in the skull. Compared with these two genera, the palate is particularly broad (especially at the anterior end because the distance M¹–M¹ is greater than M³–M³), the comparatively robust zygomatic arches flair outwards to a greater extent, the rostrum is long and narrow, and the interorbital constriction is narrow (Figure 32). The single species is *Malacothrix typica*.

D. C. D. Happold

Figure 32. Skull and mandible of *Malacothrix typica* (BM 68.52). Details of the anterior cusps of upper M₁ are obscure in this specimen.

Malacothrix typica LONG-EARED MOUSE

Fr. Souris à grandes oreilles; Ger. Großohrmaus

Malacothrix typica (A. Smith, 1834). S. Afr. Quart. J. 2: 148. Graaff Reinet District, Eastern Cape Province, South Africa.

Taxonomy Originally described in the genus *Otomys*. Synonyms: *damarensis*, *egeria*, *fryi*, *harveyi*, *kalaharicus*, *molopensis*. Subspecies: six have been described but they are of doubtful validity (Meester *et al.* 1986) and are not recognized here. Chromosome number: 2n = 38 (W. R. Harrison pers. comm.).

Description Very small mouse with large ears and short tail. Pelage soft and long (up to 8 mm). Dorsal pelage brindled creamy-grey, greyish-brown to reddish-buff; hairs dark grey at base with creamy-grey subterminal band and black tip. Black-tipped hairs result in darker patches and streaks on back to base of tail (very prominent), and on each rump. Flanks paler with fewer black-

tipped hairs. Ventral pelage pale grey to white. Head with large eyes. Ears very large, rounded at tip, naked and darkly pigmented; small patch of short creamy-yellow hairs at base of each ear. Lips and chin whitish. Limbs short and delicate. Forefoot with four digits. Hindfoot with four functional digits (Digits 2, 3, 4 and 5) (cf. *Dendromus* spp.). Tail short (ca. 45% of HB) and naked. Skull delicate; each upper incisor with groove on anterior face; M¹ relatively large (cf. M² and M³), wide palate and large curving zygomatic arches (see also profile Genus *Malacothrix*). Nipples: 2 + 2 = 8.

Geographic Variation Colour of pelage varies throughout range: dorsal pelage reddish-brown well streaked with black in

southern part of range in South Africa, pale buffy-brown in west in Namibia, and buffy-grey to reddish-buff in Botswana. Hairs of ventral pelage grey at base in eastern part of range, and pure white in the west (Smithers 1983).

Similar Species

Dendromys spp. Ears smaller; tail relatively longer (always longer than HB); dark mid-dorsal line, and without dark patches on back and rump; long prehensile tail; modified hindfoot with five digits (for climbing grass stems).

Steatomys spp. No mid-dorsal stripe or patches; hindfoot with five digits; ears shorter; body very fat at some times of year due to fat deposits under the skin and around other tissues.

Distribution Endemic to Africa. South-West Arid BZ and adjacent grasslands. Recorded from most of South Africa (except KwaZulu–Natal), Namibia, S Botswana and extreme SW Angola (De Graaff 1981).

Habitat Semi-arid grass savanna and succulent scrublands especially where substrate is hard and covered with pebbles, and where annual rainfall is 70–550 mm. In Botswana, and the Karoo of South Africa, lives near pans where there is a cover of karoo bushes. In the Kalahari Gemsbok N. P., lives on the flats and slopes of dry river banks, and on raised plateaux in the river bed but not on the duneveld nor in *Acacia* savanna (Nel & Rautenbach 1975). In the Karoo, also lives on rocky plains (J. Nel pers. comm.).

Abundance Uncommon or rare. Distribution records are scattered, and individuals are rarely caught in conventional traps but may be seen in the light of a spotlight. In the Kalahari Gemsbok N. P., where *Gerbillurus paeba* was the commonest small mammal (62% of captures), they formed only 0.35% of trappable small rodents (total $n = 1143$) (Nel & Rautenbach 1975).

Adaptations Terrestrial and nocturnal. The method of constructing a burrow is unusual: a burrow, 20–25 mm in diameter, is excavated deep into the soil. A nest chamber is built at the end of this burrow and the soil is pushed backwards to block the entrance. A new burrow is then excavated vertically to the surface ending in a tiny entrance hole. The soil from this new burrow is pushed back into the original burrow, which is now completely blocked. Nest chamber is lined with grass, and sometimes with feathers. In captivity, highest rate of activity is 19:00h to 04:00h. Well adapted for arid conditions: Tb is maintained at 37 °C even at low Ta, metabolic rate is low and 42% below predicted value, and conductance is low. When threatened, remains motionless (rather than running away); the blackish patches on the greyish-brown background probably provide cryptic camouflage (Knight & Skinner 1981).

Foraging and Food Herbivorous, primarily green vegetation and seeds (Smithers 1971). Individuals forage at least 100 m from the burrow entrance (Smithers 1971). In the Karoo, diet averaged 16% seeds, 72% herbage and 12% insects on a year-long basis ($n = 6$); this diet was very similar to three parapatric species – *Gerbillus paeba*, *Rhabdomys pumilio* and *Mus minutoides* (Kerley 1992). Competition between the four species was minimized because of differences in size and time of activity.

Social and Reproductive Behaviour Solitary and probably asocial (Nel 1975).

Reproduction and Population Structure In Botswana (Smithers 1971), young are born mainly during the warm wet months of the year (Aug–Mar); gestation: 22–26 days and litter-size (in captivity): 3.2 (2–6, $n = 10$). In South Africa (Knight & Skinner 1981), gestation: 23–25 days and litter-size: 4.0 (2–8, $n = 9$). At birth, young naked and blind; weight 1.1 g. Ear pinna free Day 6. External auditory meatus open Day 15. Weaned Day 32. Sexually active Day 70. Adult weight ca. Day 90. First litters for two ♀♀ at Day 102 and Day 120. Females have postpartum oestrus.

Predators, Parasites and Diseases Preyed upon by Barn Owls *Tyto alba* (Nel & Nolte 1965) and probably by smaller carnivores and snakes (De Graaff 1981). Several species of fleas (belonging to the families Pulicidae, Hystrichopsyllidae and Chimaeropsyllidae) have been recorded. The species is perhaps a reservoir for plague (De Graaff 1981).

Conservation IUCN Category: Least Concern.

Probably not threatened because of wide geographic range and because the preferred habitat is not utilized by humans.

GENUS *Megadendromus*

Bale Mouse

Megadendromus Dieterlen and Rupp, 1978. Z. Säugetierk. 43: 129. Type species: *Megadendromus nikolausi* Dieterlen and Rupp, 1978.

Megadendromus nikolausi.

Monospecific genus restricted to the highlands of Ethiopia. The genus is similar to *Dendromus* but is larger (mean HB: 117 mm, cf. mean HB: ca. 80 mm in the largest *Dendromus*) with a relatively short tail (ca. 80% of HB, cf. 100–160% in *Dendromus*), and with two lingual cusps on M^1 and on M^2 . *Megadendromus* is one of the core genera (with *Dendromus*) of the Dendromurinae (Musser & Carleton 2005), and is part of the clade that includes *Dendromus*, *Steatomys* and *Malacothrix* (Denys *et al.* 1995). Further details are given in the profile Subfamily Dendromurinae and species profiles. The single species is *Megadendromus nikolausi*.

D. W. Yalden

Megadendromus nikolausi BALE MOUSE (NIKOLAUS'S AFRICAN CLIMBING MOUSE, GIANT CLIMBING MOUSE)

Fr. Souris des montagnes Bale; Ger. Riesenklettermaus

Megadendromus nikolausi Dieterlen & Rupp, 1978. Z. Säugetierk. 43: 129. South of Goba, Bale Mts, Ethiopia.

Figure 33. Skull and mandible of *Megadendromus nikolausi* (SMNS 23982, after original photograph by F. Dieterlen).

Taxonomy *Megadendromus* is a monospecific genus, distinguished by large size and dental characters from *Dendromus*. Synonyms: none. Chromosome number: not known.

Description Distinctive small dendromurine, with a strong mid-dorsal stripe, moderate size and tail somewhat shorter than HB. Pelage closely resembles *Dendromus melanotis*. Dorsal pelage deep brown with a strong mid-dorsal black stripe running from behind the ears to the base of the tail. Flanks slightly brighter than back. Ventral pelage greyish-brown, velvety in texture, slightly reddish on the front and sides of the chest. Fore- and hindfeet silvery-grey; forefoot with only three functional digits (as in *Dendromus*, cf. other genera in the subfamily); hindfoot with five digits, Digit 5 with nail (as in some *Dendromus* spp.). Ears lightly furred, brownish-grey. Very slight dark hair around the eyes, insufficient to produce a spectacled effect as in *D. melanotis*. Tail relatively long (ca. 80% of HB), rather thin; dark mid-dorsally due to dark bristles but greyish-white on sides and below. Apart from its larger size (cf. *Dendromus* spp.), the skull is also distinctive in having additional internal cusps on rows two and three of M^1 and M^2 (see Dieterlen & Rupp 1978) (Figure 33).

Geographic Variation None recorded.

Similar Species

Dendromus melanotis. Much smaller; tail 120% of HB.

Dendromus lovati. Much smaller, with three distinctive black stripes on back and rump.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Confined to the high plateaux of SE Ethiopia, from 3000 to 3900 m. Known from only two localities, Dinshu in Bale and Mt Chilalo in Arssi (Dieterlen & Rupp 1978).

Habitat *Hagenia-Erica arborea* forest and *Erica arborea* scrub and forest (Dieterlen & Rupp 1978). Lives in same habitat as *Stenocephalemys griseicauda*, *Lophuromys flavopunctatus*, *Otomys typus* and *Dendromus melanotis*.

Abundance Rare, only 4 specimens known (Dieterlen & Rupp 1978, Demeter & Topál 1982). Collecting in Ethiopia during 1968–98 (n = ca. 6300 rodents) yielded no individuals of this species.

Remarks Presumably nocturnal. The large size and shorter tail of Bale Mice suggest that they may not be arboreal (cf. *Dendromus*). These characters may also be adaptations to the cold conditions at high altitudes. Presumably granivorous; detailed information not available. Some of the specimens came from owl pellets.

Conservation IUCN Category: Data Deficient.

Distribution is in an area where all woodland is being cleared very rapidly by the increasing human population. The species is undoubtedly threatened; the very limited range and rarity suggest it should be classified as Endangered. Schlitter (1989) listed it as rare.

GENUS *Prionomys* Bates's Climbing Mouse

Prionomys Dollman, 1910. Ann. Mag. Nat. Hist., ser. 8, 6: 226. Type species: *Prionomys batesi* Dollman, 1910.

Prionomys is a monotypic genus recorded only from rainforest habitats in Cameroon, Central African Republic and Congo. The genus is closely related to *Dendromus* and *Dendroprionomys* (Dollman 1910, Petter 1966b). The genus shares some characters with *Dendromus* and *Dendroprionomys* such as arboreal habit, small size and semi-prehensile tail. The forefoot has four functional digits (Digits 2, 3, 4 and 5) and a short stumpy non-functional Digit 1 (as in *Dendroprionomys*). The hindfoot has five digits; Digit 1 is opposable and Digit 5 is non-opposable (Figure 30) (cf. *Dendromus* and *Dendroprionomys*). The incisor teeth are pro-odont (cf. *Dendromus*, *Dendroprionomys*), and the cheekteeth have tall pointed cusps (as in *Dendroprionomys*). Additional details are given in the subfamily and species profiles. The single species is *Prionomys batesi*.

Christiane Denys

Prionomys batesi.

Prionomys batesi BATES'S CLIMBING MOUSE (DOLLMAN'S TREE MOUSE)

Fr. Souris arboricole de Bates; Ger. Bates Klettermaus

Prionomys batesi Dollman, 1910. Two new African mammals. Ann. Mag. Nat. Hist., ser. 8, 6: 226. Dja River, Bitye, Cameroon. 2000 ft (618 m).

Taxonomy Closely related to *Dendromus* and *Dendroprionomys* (see genus profiles). Synonyms: none. Chromosome number: not known.

Description Very small mouse with long tail. Pelage short, dense, soft and woolly. Dorsal pelage brownish-grey; hairs dark grey at base, brown at tips. Mid-dorsal stripe absent. Flanks pale grey; hairs dark grey at base, pale grey at tips. Ventral pelage pale grey, similar to flanks; hairs grey at base, paler at tips. Head similar in colour to dorsal pelage. Conspicuous brown eye-ring. Long stiff vibrissae. Ears moderate, darkly pigmented, with sparse brown hairs. Chin, throat and chest grey. Limbs short, with few short hairs. Forefoot with four digits: Digit 1 absent, Digits 2, 3, 4 and 5 thin, each with small pale claw. Large carpal tuberosity on 'hand'. Hindfoot with five digits: Digit 1 shorter than other digits, with 'nail-like' claw, Digits 2, 3, 4 and 5 long and thin, each with small claw; Digit 1 opposable (cf. Digit 5 opposable in *Dendromus* and *Dendroprionomys*) (Figure 30); three large callosities at base of digits on hindfoot. Tail long (ca. 122% of HB), brown, with scales arranged in rings; few (if any) small bristles. Skull: upper incisors pro-odont without longitudinal grooves, braincase globular-shaped, molar teeth with tall pointed cusps (Figure 34). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Dendromus spp. Cheekteeth molariform; incisor teeth orthodont.

Dendroprionomys rousseloti. Cheekteeth with tall pointed cusps; incisor teeth orthodont.

Distribution Endemic to Africa. Rainforest BZ (West Central Region, Gabon Sub-region). Recorded from Cameroon, S Central African Republic and W Congo (Odzalla).

Habitat Rainforest, especially where there are small shrubs and lianas.

Abundance Uncertain; known only from a few specimens at five localities.

Adaptations Terrestrial and arboreal. Bates's African Climbing Mice climb on thin branches, twigs and lianas using the prehensile tail, long digits, callosity on the forefoot and opposable Digit 1 of hindfoot (in a similar way to *Dendromus* spp.). Burrows are made by digging in forest soil using the pro-odont upper and lower incisor teeth; each burrow is indicated by a little hillock of soil, ca. 30 cm diameter, without a visible entrance hole. The burrow contains a small nest chamber lined with dry leaves. Activity is entirely nocturnal: one individual emerged at 21:00h (three hours after nightfall) and climbed rapidly into nearby shrubs and lianas. Activity alternated between climbing (and foraging) in the forest and 15-minute 'rest' periods in the nest (F. Petter unpubl.). Bates's African Climbing Mice emit a strong odour, not unlike that of some species of shrews.

Figure 34. Skull and mandible of *Prionomys batesi* (BMNH 11.5.5.9, holotype).

Prionomys batesi

Foraging and Food Insectivorous. The diet consists (almost exclusively) of leaf-nesting ants, as well as spiders. The ants are captured with the tongue and crushed by the sectorial cusped cheekteeth. Large quantities of prey are consumed (F. Petter unpubl., Genest-Villard 1980).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Young are born in a nest chamber, lined with leaves, under the soil (see above).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Data Deficient.

Considered as Rare by Schlitter (1989). The very small geographic range and presumed rarity are cause for concern.

GENUS *Steatomys*

Fat Mice

Steatomys Peters, 1846. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 11: 258. Tete, Mozambique. Type species: *Steatomys pratensis* Peters, 1846.

Steatomys pratensis.

This exclusively African genus is widespread on the continent south of the Sahara and currently eight species are recognized. Four species are confined to West and sub-Saharan Africa, while the other four species occur in southern, central and East Africa. Species in the genus inhabit a variety of savanna habitats.

Species of the genus are small with soft shiny unpatterned dorsal pelage ranging in colour from pale grey-brown to brownish-buff. Ventral pelage is pure white. Tail is short, usually 50–60% of head-body length. Muzzle is pointed and ears are rounded. Limbs are short with white feet. Forefeet have four well-developed digits (Digit 1 absent), and hindfeet have five well-developed digits. All digits have long, sharp claws, which may be employed in the digging of burrows. Characteristics of the skull include orthodont incisors; each upper incisor with a single shallow groove on the outer face (usually paler in colour than the ungrooved part); zygomatic plate small and vertical (as in *Dendromys*) with a masseteric tubercle at lower anterior corner (also as in *Dendromys*); auditory bullae relatively large; palate wide, widest at level with upper M¹ and narrowest at level with upper M³; and ungrooved lower incisors. M¹ is the largest molar. M³ is greatly

Figure 35. Skull and mandible of *Steatomys jacksoni* (HC 2797).

reduced (Figure 35). Species of this genus are readily identified by their rotund shape, short tail and grooved upper incisors.

A well-known character of all species in the genus is the ability to lay down substantial amounts of subcutaneous fat (hence the common name 'fat mouse'), a feature which allows them to enter torpor readily during cold conditions. Hibernation, however, does not occur, and individuals may be active throughout the year. All members of this genus are terrestrial and nocturnal. They construct their own burrows, which may be simple or relatively complex. Some

burrows have multiple entrances (some of which may be plugged) as well as a nest chamber. On account of their high fat content, fat mice are widely consumed by humans.

Historically, at least 18 species have been recognized (Musser & Carleton 2005). Coetzee (1977) provisionally acknowledged only three species. The taxonomic status of the genus is still unclear, as evidenced by the changing number of species. There is less controversy over the three West African species (revised by Swanepoel & Schlitter 1978), but the taxonomic status of the taxa in other parts

of Africa is unclear (see Coetzee 1977, Meester *et al.* 1986). Musser & Carleton (1993) recognized six species (*S. caurinus*, *S. cuppedius*, *S. jacksoni*, *S. krebsi*, *S. parvus*, *S. pratensis*), and more recently (2005) added *Steatomys bocagei* and *Steatomys opimus* (previously both synonyms of *S. pratensis*).

Species in the genus are distinguished by size, number of nipples and geographic distribution (Table 17).

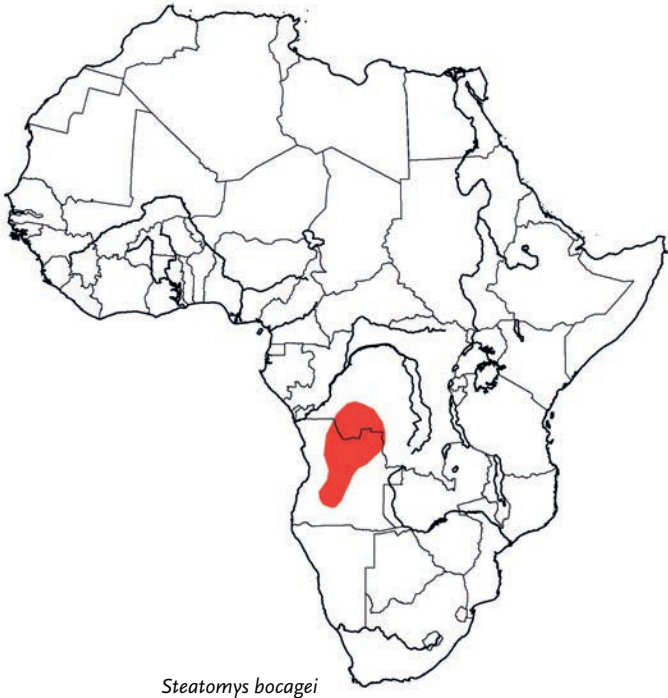

A. Monadjem

Steatomys bocagei **BOCAGE’S FAT MOUSE**
Fr. Souris adipeux de Bocage; Ger. Bocages Fettmaus

Steatomys bocagei Thomas, 1892. Ann. Mag. Nat. Hist., ser. 6, 10: 264. Caconda, Angola.

Taxonomy Referred to as *S. bocagei* by Hill & Carter (1941) and Ellerman *et al.* (1953), but considered to be a synonym of *S. pratensis* by Coetzee (1977) and Musser & Carleton (1993). However, the

presence of four pairs of nipples (Crawford-Cabral 1998) and the much larger size compared with *S. pratensis* warrants recognition of *bocagei* as a valid species (see Musser & Carleton 2005). Synonyms: *kasaicus*. Subspecies: none. Chromosome number: not known.

Description Small to medium-sized mouse, but one of the largest species of *Steatomys*. Dorsal pelage dull reddish-brown; hairs dark grey at base, brownish at tip. Ventral pelage pure white. Colour of ventral pelage well delineated from dorsal pelage. Muzzle, and area between eye and ear, cinnamon; lips white. Throat white. Ears short. Inner surfaces of limbs and feet white. Forefeet with four digits; Digit 1 absent, Digit 5 shorter than Digits 2, 3 and 4; claws long. Hindfeet short and broad with five digits; Digits 2, 3 and 4 much longer than Digits 1 and 5. Tail short (ca. 50% of HB), hairy, brown above, white below. Skull: large, with narrow interorbital region, and wide opisthodont upper incisors, each with single groove. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species
S. pratensis. Smaller; tail bicoloured, brown above, pale below; nipples variable, but usually 10–14 nipples in 5–7 pairs; probably parapatric in east of range.

S. opimus. Similar size; dorsal pelage grey; tail dark brown above, white below; nipples 2 + 3 = 10; distribution Cameroon to SW Sudan.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded from the Central Plateau of Angola (Crawford Cabral 1998) and eastward to SC DR Congo (Musser & Carleton 2005). Sympatric with *S. pratensis* in N Angola.

Habitat Grasslands in moist savannas and woodlands.

Abundance Common (Sanborn 1952, as *S. pratensis kasaicus*), although known from only a few localities.

Remarks Specimens very fat in the dry season (Sanborn 1952), suggesting a metabolism similar to that of other *Steatomys* spp. (see profiles Genus *Steatomys* and *S. opimus*). Digs its own burrow, and makes nest in burrow. After burning of the savanna, only ♀♀ captured (Sanborn 1952). Eaten by local people (Sanborn 1952) because of their high fat content.

Conservation IUCN Category: Least Concern.

Steatomys caurinus NORTH-WESTERN FAT MOUSE

Fr. Souris adipeux du Nord-Ouest; Ger. Nordwestlicher Fettmaus

Steatomys caurinus Thomas, 1912. Ann. Mag. Nat. Hist., ser. 9, 9: 271. Panyam, Nigeria. 4000 ft (1400 m).

Taxonomy Listed as a subspecies of *S. pratensis* by Coetzee (1977), but considered a valid species by Rosevear (1969) and Swanepoel & Schlitter (1978). Synonyms: *roseveari*. Subspecies: none. Chromosome number: 2n = 72 (Mali; B. Sicard & L. Granjon unpubl.).

Description Small mouse with coarse hairs and with short tail. Dorsal pelage medium-brown to reddish-brown, usually darker on mid-dorsal region; hairs grey at base, brown at tip. Flanks paler. Ventral pelage pure white, clearly delineated from colour of flanks. Nose pointed. Ears large and rounded, with longish hairs, especially on outer surface. Forefeet and hindfeet short, white. Tail short (ca. 38% of HB; range 16–54%), sparsely haired, brown above, white below. Individuals may be very fat at some periods of the year. Skull: interparietal bone small (length 3.5 mm or less). Nipples: number variable, always >8 (Coetzee 1977).

Geographic Variation None recorded.

Similar Species

S. cuppedius. Smaller size, pelage pale, hairs soft; tail relatively longer (51–57% of HB).

S. jacksoni. Same size as the largest *S. caurinus*, pelage dark brown, hairs soft; tail usually relatively longer (ca. 50% of HB); length of interparietal bone ca. 4.5 mm.

Distribution Endemic to Africa. Sudan and Guinea Savanna BZs. Recorded from Senegal, Mali, Burkina, N Côte d'Ivoire, N Ghana, Togo, Benin, NW Nigeria; eastern limits uncertain (Swanepoel & Schlitter 1978; B. Sicard & L. Granjon unpubl.).

Steatomys caurinus

Habitat Drier savannas on sandy soils, where vegetation cover is poor. Often found in traditionally cultivated fields and fallow lands.

Abundance Apparently uncommon, perhaps due to low trappability; specimens obtainable only through excavations of burrows. Infrequently found in pellets of Barn Owls *Tyto alba* in Senegal (L. Granjon, K. Ba & J.-M. Duplantier unpubl.).

Adaptations Nocturnal and terrestrial. Individuals accumulate fat during the wet season, which allows them to go into torpor and to be inactive during the dry season. In laboratory conditions, appears better adapted to dehydration than gerbils (Lacas *et al.* 2000).

Foraging and Food No information.

Social and Reproductive Behaviour Generally only one adult individual per burrow.

Reproduction and Population Structure Females with their young recorded in 11 burrows in Sep and Oct in S Mali; in each burrow, mean number of young 8.5 (range 5–12, $n = 11$) (B. Sicard & L. Granjon unpubl.).

Predators. Parasites and Diseases Found in pellets of Barn Owls *Tyto alba* in Senegal (Heim de Balsac 1965; Granjon, Bâ & Duplantier unpubl.).

Conservation IUCN Category: Least Concern.

Steatomys cuppedius DAINY FAT MOUSE

Fr. Souris adipeux gracile; Ger. Zierliche Fettmaus

Steatomys cuppedius Thomas and Hinton, 1920. Novit. Zool. 27: 318. Farniso near Kano, Nigeria. 1700 ft (518 m).

Taxonomy Although listed as a subspecies of *S. parvus* by Coetzee (1977), most authors (e.g. Rosevear 1969, Swanepoel & Schlitter 1978, Musser & Carleton 1993, 2005) consider *cuppedius* to be a valid species. Synonyms: none. Chromosome number: not known.

Description Small, delicate mouse with soft silky pelage and short white tail; the smallest of the West African species. Dorsal pelage pale, sandy to grey; hairs medium grey at base, sandy or grey at tip; darker on mid-dorsal line due to some black-tipped hairs. Ventral

pelage pure white. Nose pointed. Ears large and rounded. Nasal region, cheeks, lips and throat white. Forefeet and hindfeet white. Tail short (57% of HB, range: 51–67%), white, scantily covered with white hairs above and below. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

S. caurinus. Larger size, pelage darker, hairs coarse; tail relatively short (mean 38% of HB).

Distribution Endemic to Africa. Sudan Savanna BZ. Recorded from several localities in Senegal, and also from N Nigeria and S Niger. Swanepoel & Schlitter (1978) expressed doubts about data concerning Senegal (Heim de Balsac 1965) but captures (in Mbour) and in owl pellets from various localities (L. Granjon, K. Ba & J.-M. Duplantier unpubl.) confirm the presence of the species in Senegal. May occur also in other parts of the Sudan Savanna BZ between these known localities. Records of this species from SE Ghana are now known to be *Uranomys ruddi* (see Grubb *et al.* 1998 for details).

Habitat In Senegal, trapped in sandy areas near gardens and near the coast. Seems to prefer drier habitats than *S. caurinus*.

Abundance Generally uncommon, but may be locally abundant: e.g. in Nigeria, 55 individuals caught within a week in a single locality (as *S. parvus*; Happold 1987), and in Senegal 12 individuals caught within two weeks on the same trap line. Comprised up to 30% of prey in pellets of Barn Owls *Tyto alba* in some localities in Senegal (L. Granjon, K. Ba & J.-M. Duplantier unpubl.).

Steatomys cuppedius

Adaptations Nocturnal and terrestrial. Individuals accumulate fat during the wet season, which allows them to go into torpor or to be inactive during the dry season.

Foraging and Food No information.

Social and Reproductive Behaviour Several individuals caught at the same place suggests the existence of colonies.

Reproduction and Population Structure No detailed information. Juveniles (HB: 58–62 mm) in Dec in N Nigeria (labels, BMNH). In Mbour (Senegal), sex-ratio in Aug was 10 ♂♂ : 2 ♀♀ for individuals caught at the same place within a few days.

Predators, Parasites and Diseases Preyed on by Barn Owls *Tyto alba* in Senegal (Heim de Balsac 1965; L. Granjon, K. Ba & J.-M. Duplantier unpubl.).

Conservation IUCN Category: Least Concern.

Steatomys jacksoni JACKSON'S FAT MOUSE

Fr. Souris adipeux de Jackson; Ger. Jacksons Fettmaus

Steatomys jacksoni Hayman, 1936. Proc. Zool. Soc. Lond. 1935: 930 (publ. 1936). Wenchi, Ghana.

Taxonomy Included in *S. caurinus* by Coetzee (1977) but retained as a distinct species by Swanepoel & Schlitter (1978) and Musser & Carleton (1993). The wide interparietal bone on the skull (compared with other species in the genus) is the diagnostic character for the species, but the significance of this character is uncertain. The validity of the species can not be assessed until additional specimens are available (Musser & Carleton 1993). Synonyms: none. Chromosome number: not known.

Description Small dark brown mouse, with a short tail and tendency to be fat (or very fat) at some seasons of the year. Pelage soft. Dorsal pelage dark brown; dorsal hairs dark slate-grey at base, medium-brown at tip. Ventral pelage pure white. Chin, throat, chest white. White postauricular spot, sometimes obscure. Fore- and hindlimbs and feet white. Forefoot with four well-developed digits. Tail short (ca. 50% of HB), bicoloured, dark above, whitish below. Skull with small cheekteeth (and M³ very small), palate not much prolonged posteriorly to cheekteeth, each upper incisor opisthodont with single groove and angled slightly outwards, and moderately well-developed auditory bullae; interparietal bone ca. 4.5 mm (cf. *S. caurinus*). Nipples: 2 + 4 = 12.

Geographic Variation None recorded.

Similar Species

S. caurinus. Dorsal pelage rufous-brown and paler; usually smaller, HB: 79–122 mm, HF: 14–18 mm, GLS: 19–27 mm; interparietal bone 3.0–3.5 mm; Guinea and Sudan Savanna BZs; may be parapatric with this species.

S. cuppedius. Dorsal pelage sandy-grey; smaller, HB: <90 mm, HF: 15–17, GLS: <24 mm; Sudan and Sahel Savanna BZs.

Mus musculoides. Dorsal pelage golden-brown to dark brown; much smaller (HB: 55–70 mm, HF: 12–14 mm, GLS: 18–20 mm);

Steatomys jacksoni

Guinea and Sudan Savanna BZs, and savanna habitats in Rainforest–Savanna Mosaics.

Distribution Endemic to Africa. Guinea Savanna BZ and Northern Rainforest–Savanna Mosaic. Recorded only from W Ghana and SW Nigeria. Two young animals from Wulehe, Togo perhaps represent this species (Rosevear 1969). The species was not recorded by Robbins & Van der Straeten (1996) in Togo and Benin, although another species of *Steatomys* (*S. caurinus*) was recorded.

Habitat At Olokomeji F. R., SW Nigeria, specimens were caught in tall grasslands with *Lophira lanceolata*, *Buterospermum paradoxum*, *Burkea africana* and *Daniella oliveri* trees; these grasslands were burned regularly in the early to mid-dry season (Anadu 1973). The holotype, from Wenchi, Ghana, was collected 'in open country, the completely destroyed edge of the high forest' (Rosevear 1969).

Abundance Very rare. Specimens are recorded only from one locality in Ghana and two localities in Nigeria (and possibly one locality in Togo). At Olokomeji, SW Nigeria, only eight individuals (Anadu 1979b) were captured on two study areas in two and half years, representing <0.01% of the small mammals ($n = 803$) (Anadu 1973); no other species of *Steatomys* was present.

Remarks Nocturnal and terrestrial. It seems likely that this species is similar to other species in the genus, i.e. digs extensive burrows, stores body fat when food is abundant and enters torpor when conditions are unfavourable. Anadu (1979b) recorded, that after capture, individuals curled up with their eyes closed and made a high pitched 'Kweee-kweee' vocalization – a response unlike that of any of the other sympatric small rodents.

Conservation IUCN Category: Data Deficient.

The rarity, fragmentation of populations, and lack of data make it very difficult to assess the category for this species.

Measurements

Steatomys jacksoni

HB: 101 (90–112) mm, $n = 3$

T: 51 (44–58) mm, $n = 3$

HF: 18.3 (18–19) mm, $n = 3$

Nigeria (Anadu 1979b)

The holotype, an old individual, was larger in some dimensions (HB: 120 mm, E: 18 mm, GLS: 28.9 mm, GWS [Zygomatic breadth]: 13.0 mm) than those given above (Rosevear 1969).

Key References Anadu 1979b; Rosevear 1969.

D. C. D. Happold

Steatomys krebsii KREBS'S FAT MOUSE

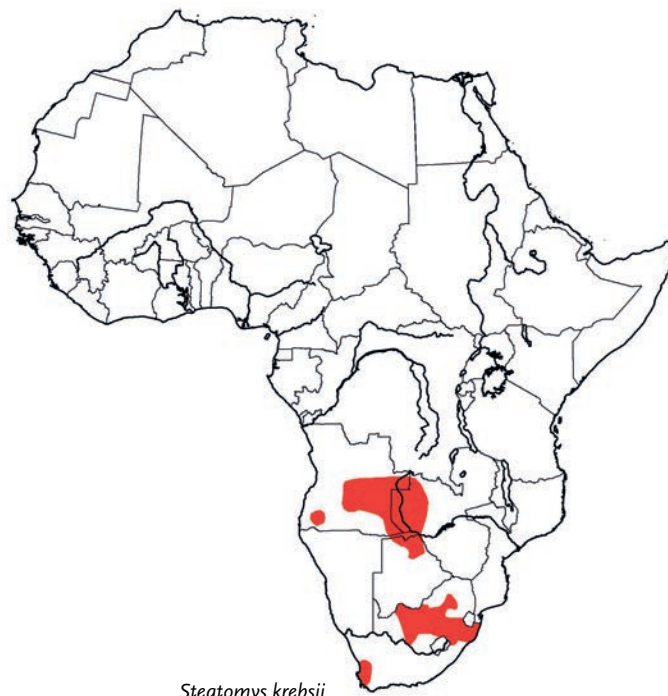

Fr. Souris adipeux de Krebs; Ger. Krebs Fettmaus

Steatomys krebsii Peters, 1852. Reise nach Mozambique, Säugethiere, p. 165. 'Kaffraria', South Africa.

Taxonomy Currently, only size and colour of tail separates *S. krebsii* from *S. parvus*, neither feature differing consistently between the two species. This has resulted in specimens from N KwaZulu–Natal Province, South Africa, having been assigned successively to one species or the other. Pending further investigation, they are considered here to belong to *S. krebsii* (Taylor 1998). Taxonomic relationships between the three or four disjunct populations need further study. Synonyms: *angolensis*, *bensoni*, *bradleyi*, *chiversi*, *mariae*, *orangiae*, *tongensis*, *transvaalensis*. Subspecies: none. Chromosome number: not known.

Description Small plump mouse with soft, shiny pelage. Dorsal pelage and flanks orange-buff to greyish-brown and dark brown; hairs with grey base, brown at tip; many black-tipped hairs, especially on upper part of back. Ventral pelage white; hairs pure white or grey at base with white tip. Head with pointed nose and long vibrissae. Ears small and rounded, brownish, with longish hairs on outer surface. Lower cheek, lips, chin and throat white. Limbs short. Feet white, each digit with long, sharp claw. Tail short (ca. 60% of HB), brownish above, white below. Nipples: $2 + 2 = 8$.

Geographic Variation Meester *et al.* (1986) recognized four subspecies in southern Africa, but the validity of subspecies is dubious. The form *pentonyx* (from Western Cape Province, South Africa) is distinguishable by white at base of ventral hairs. In South Africa, dorsal pelage orange-buff to pale brown; in Zambia, dorsal pelage brown to dark brown.

Steatomys krebsii

Similar Species

S. pratensis. On average slightly larger; nipples variable, but usually 10–14 nipples in 5–7 pairs.

S. parvus. On average smaller, tail white above and below; dorsal pelage pale buff in area of sympatry; nipples $2 + 2 = 8$.

Distribution Endemic to Africa. Zambezian Woodland, Highveld and South-West Cape BZs. Distribution disjunct. Recorded from three separate areas: (a) Angola, Botswana, W Zambia (Smithers 1971, Ansell 1978, Crawford-Cabral 1998), (b) Free State, Northwest and KwaZulu–Natal Provinces, South Africa, and (c) Western and Eastern Cape Provinces, South Africa (De Graaff 1981).

Habitat Tolerates a wide range of habitats on sandy to loamy soils. More moisture-tolerant than *S. pratensis* (Coetzee 1977).

Abundance Uncertain; poorly represented in museum collections.

Adaptations Terrestrial and nocturnal. Constructs burrows that tend to spiral downwards (De Graaff 1981).

Foraging and Food Probably granivorous (De Graaff 1981), although the stomach contents of a single specimen from South Africa consisted entirely of insect remains (Rautenbach & Nel 1980).

Social and Reproductive Behaviour Not communal (De Graaff 1981).

Reproduction and Population Structure Pregnant ♀ with five embryos (South Africa; Rautenbach *et al.*, 1981). Female with four young in Oct (Zambia; n = 2; labels BMNH).

Predators, Parasites and Diseases Populations may be infested sporadically with plague (De Graaff 1981).

Conservation IUCN Category: Least Concern.
Listed as ‘rare’ in KwaZulu–Natal (Taylor 1998).

Steatomys opimus POUSARGUES’S FAT MOUSE

Fr. Souris adipeux de Pousargues; Ger. Pousargues Fettmaus

Steatomys opimus Pousargues, 1894. Bull. Soc. Zool. de France, 19: 131. Balao, Central African Republic.

Taxonomy Considered to be either a valid species (Genest-Villard 1979, Musser & Carleton 2005) or a subspecies of *S. pratensis* (Coetzee 1977, Musser & Carleton 1993). Larger body size, larger on average skull size and reduced number of nipples compared with *S. pratensis*, supports specific status. Relationship with *S. bocagei* from Angola and S DR Congo (also larger than other species in the genus) warrants investigation. Synonyms: *gazellae*. Subspecies: none. Chromosome number: not known.

Description Small to medium-sized mouse, but one of the largest species of *Steatomys*. Often plump and rotund (due to extensive deposits of fat) with short limbs and tail. Pelage short and soft. Dorsal pelage and flanks grey or brown. Ventral pelage white. Head grey, throat white, lips white. Ears relatively long. Limbs short, grey; digits white with long white claws. Tail short (ca. 35% of HB), dark brown above, white below. Nipples: 2 + 3 = 10.

Geographic Variation None recorded.

Similar Species

S. bocagei. Similar size; dorsal pelage reddish-brown; tail ca 50% of HB; nipples 2 + 2 = 8; Angola and SW DR Congo.

Steatomys opimus

S. parvus. Smaller; dorsal pelage pale buff; tail white above and below; nipples 2 + 2 = 8; distribution to the east and south, may be parapatric in extreme east of range.

Distribution Endemic to Africa. Guinea Savanna BZ (western part) and Northern Rainforest–Savanna Mosaic; records disjunct. Recorded from Cameroon, S Central African Republic, N DR Congo and extreme SW Sudan (Musser & Carleton 2005).

Habitat Savanna habitats interspersed with forest relicts. Prefers sandy soils on valley slopes above riverine forest, with dense grasses (up to 4 m before burning) and termite mounds. In Central African Republic, densest populations found in savanna grasslands that are burned regularly and where there are small trees (especially *Hymenocardia acida* and *Amona senegalensis*) (Genest-Villard 1979).

Abundance Generally uncommon or rare; locally dense populations in favoured habitats.

Adaptations Terrestrial and nocturnal. Excavates complex burrow with entrance of 3–4 cm diameter. Spherical nesting cavity, 30–50 cm from entrance, filled with shredded interlaced grass leaves that completely fill the nesting chamber (10–15 cm diameter). Nest situated 7–15 cm below soil surface. Beyond nest, burrow spirals downwards in 1–3 complete spirals to a depth of 70–100 cm below soil surface; spiral may be open or filled with loose sand, and ends with small open ‘cul-de-sac’. Burrow length: 1.5–3 m. Temperature in nest during daytime is 27–30 °C when T_a is 22–36 °C. Preferred place for burrowing is in old termitaria and in the spill-heap of an aardvark burrow; these mice do not utilize the burrows of other rodents (Genest-Villard 1979). Individuals are often ‘blanketed by a layer of fat’ (Hatt 1940a) under the skin.

In captivity, activity outside the nest is restricted to about one hour in the evening (Petter 1966d); and in the wild, individuals seem to remain in their nests at all times during the cool season (perhaps a reason why they are rarely caught in traps). During activity (in captivity), T_b is 33–34.6 °C. When resting in the nest, T_b drops to 20–27 °C, roughly following T_a ; at these temperatures, the individual is lethargic and in a state of torpor (Petter 1966d). These mice (and perhaps all *Steatomys*) have evolved an unusual strategy for survival when the environment is dry and cool: low food intake (because the diet is rich in protein and fat – see below), storage of

fat in the tissues, an ability to lower body temperature (to reduce energy expenditure), low daily activity, and daily and seasonal torpor to minimize the use of energy.

Foraging and Food Primarily insectivorous. Contents of 23 (out of 25) stomachs (collected in Feb–Jul) were exclusively termites, with a few ants and some grains of sand. Termites provide a good source of fat (see above). May be granivorous at other times of year (Genest-Villard 1979).

Social and Reproductive Behaviour Most burrows contained a single individual; some contained a mother and 2–3 young or subadults.

Reproduction and Population Structure Reproduction probably during wet season (Jun–ca. Dec) in Central African Republic. Young (ca. 2 months old) caught in Feb, and subadults found at end of dry season. Litter-size: probably 3. Young unlikely to breed in the year of birth (Genest-Villard 1979).

Predators, Parasites and Diseases Because of their high fat content, they are collected for food by local people (Hatt 1940a).

Conservation IUCN Category: Least Concern.

Steatomys parvus TINY FAT MOUSE

Fr. Petite souris adipeuse; Ger. Kleine Fettmaus

Steatomys parvus Rhoads, 1896. Proc. Acad. Nat. Sci. Philadelphia, p. 529. North shore of L. Rudolf (now L. Turkana), Ethiopia.

Taxonomy Formerly known as *Steatomys minutus*. The single Ethiopian record, given as *S. pratensis* (Yalden *et al.* 1976) was later re-identified as *S. parvus* (Yalden *et al.* 1996). The form *tongensis* from N KwaZulu–Natal Province, South Africa, has been allocated recently to *Steatomys krebsii* (Taylor 1998). Specimens recorded as *S. parvus* from N Nigeria (Happold 1987) are now considered to represent *S. cuppedius*. Taxonomic relationship between the geographically separated south-western and north-eastern populations needs to

be assessed. Synonyms: *aquilo*, *athi*, *kalaharicus*, *loveridgei*, *minutus*, *muanzae*, *swalius*, *thomasi*, *umbratus*. Subspecies: none. Chromosome number: not known.

Description Very small plump mouse with soft pelage. Dorsal pelage pale buff, with paler flanks; dorsal hairs with slaty base and rufous tip. Ventral pelage pure white to off-white. Head with pointed nose and long vibrissae. Upper lips, lower cheeks, throat and lower

shoulders white. Delineation between colour of flanks and ventral pelage more dorsal than in other species of genus. Ears small and rounded, brownish. Limbs short, feet pale. Forefeet with four well-developed digits. Hindfeet with five well-developed digits. All digits with long, sharp claws. Tail short (ca. 50% of HB), white above and below. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

S. pratensis. Usually larger; tail bicoloured, brown above, pale below; nipples variable, but usually 10–14 nipples in 5–7 pairs.

S. krebsii. Usually on average larger; tail bicoloured, greyish-brown above, pale below; nipples $2 + 2 = 8$; occurs only south of ca. 10° S latitude.

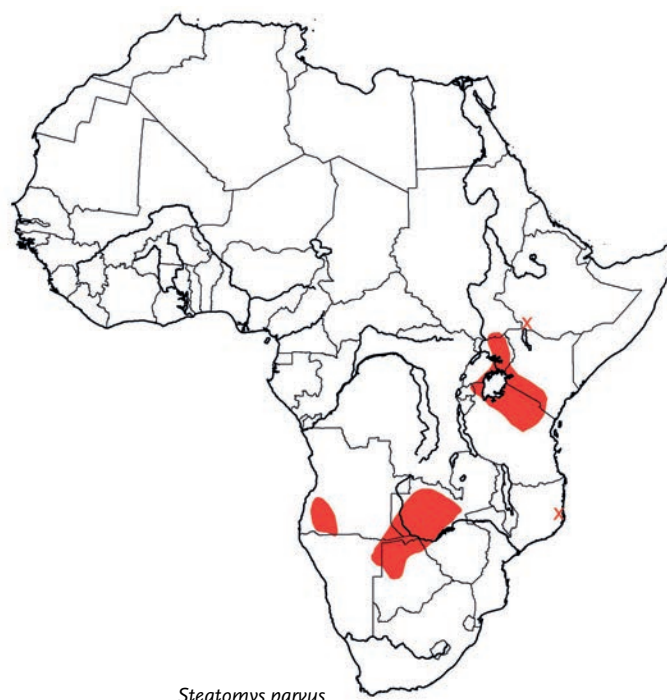

Distribution Endemic to Africa. Zambezan Woodland BZ and marginally Somalia–Masai Bushland BZ. Two, perhaps three, disjunct populations: (a) S Angola and N Namibia, (b) W Zambia and N Botswana, (c) N Tanzania through Kenya to Somalia (Funaioli & Simonetta 1966), S Ethiopia (Yalden *et al.* 1976) and east to Uganda (Wilson 1995).

Habitat Savanna on sandy soils. In Botswana, found in riverine flood-plains and woodlands, and in dry grassland with open scrub (Smithers 1971). Prefers drier habitats than *S. pratensis*. In Botswana, sympatric with *S. krebsii* and *S. pratensis* (Smithers 1971). Not recorded from moist woodlands, forests and montane grasslands.

Abundance Not known, but unlikely to occur at high densities.

Remarks Despite its wide distribution, little information available. Nocturnal and terrestrial. Excavates own burrow, which is used for nesting and food hoarding. Capable of accumulating large quantities of fat under the skin. A single lactating ♀ was collected in Nov in Botswana (Smithers 1971), suggesting that offspring are born in the wet season.

Conservation IUCN Category: Least Concern.

Steatomys pratensis COMMON FAT MOUSE

Fr. Souris adipeux commune; Ger. Gemeine Fettmaus

Steatomys pratensis Peters, 1846. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 11: 258. Tete, Mozambique.

Taxonomy The species *pratensis* is limited to the large *Steatomys* of southern, central and East Africa (Musser & Carleton 1993). Formerly, *caurinus* and *jacksoni* of West Africa were considered to be subspecies of *pratensis* (Coetzee 1977), but are now regarded as distinct species (Swanepoel & Schlitter 1978). The forms *opimus* and *bocagei* were also allocated as subspecies of *S. pratensis* (Coetzee 1977), but are now recognized as valid species (Genest-Villard 1979, Musser & Carleton 2005). Synonyms: *edulis*, *leucorhynchus*, *maunensis*, *natalensis*, *nyasae*. Subspecies: none. Chromosome number: $2n = 68$ (R. Matthey in Robbins & Baker 1978).

Description Small plump mouse with soft, shiny pelage. Dorsal pelage variable, rusty-brown, medium brown or dark brown; hairs slaty-grey at base, brown or black at tip. Flanks paler, tinged with rufous-brown. Ventral pelage pure white. Colour of ventral pelage clearly delineated from colour of flanks. Head with pointed nose and long vibrissae. Nose, chin and throat white. Ears small and rounded, brownish. Limbs short. Feet white, each digit with long sharp claw. Tail short (ca. 50% of HB) and thin, brownish above and paler below. Nipples variable, but usually 10–14 nipples in 5–7 pairs.

Geographic Variation None recorded.

Similar Species

S. parvus. Almost always smaller; tail white above and below; nipples $2 + 2 = 8$.

S. krebsii. On average smaller; tail bicoloured, greyish-brown above, pale below; nipples $2 + 2 = 8$.

Distribution Endemic to Africa. Zambezian Woodland BZ, and parts of Southern Rainforest–Savanna Mosaic and the South-West Arid BZ (Kalahari Desert). Recorded from NW Angola, Namibia, N Botswana, Zimbabwe, N South Africa, Swaziland, Mozambique, C Zambia, Malawi and STanzania. Due to past confusion with *Steatomys parvus*, distribution in East Africa is unclear. The record from owl pellets in EC Ethiopia (Demeter 1982, assessed as this species in Musser & Carleton 2005) needs verification, and is more likely to refer to *S. opimus* than *S. pratensis* (A. Monadjem unpubl.).

Habitat Grassland and woodland savannas, cultivated and fallow fields, and edges of rivers and swamps. Generally absent from forests and montane grasslands. Favours open savanna on sandy substrates, but in Swaziland may also occur on hard substrates. Appears to select recently burnt areas where there is new grass cover (Monadjem 1999b).

Abundance Relatively uncommon, but may be locally very abundant. Population densities rarely exceed 5/ha in Swaziland (A. Monadjem unpubl.).

Adaptations Nocturnal and terrestrial. Uses long claws to excavate a burrow, which is used for resting, nesting and food hoarding. Each burrow, usually up to 40 cm deep, may have more than one entrance; one burrow in southern Africa had four entrances leading to a nest chamber (De Graaff & Nel 1992). Fat mice are capable of accumulating large quantities of fat under the skin when food is abundant. Accumulated fat is used for metabolism in the dry and cold seasons. Adult ♂♂ achieve greatest body weights in wet

season (Monadjem 1999b), but remain fat throughout wet and dry seasons. In captivity, individuals readily enter torpor in cold conditions for variable durations, which are determined by the ambient temperature (Richardson & Perrin 1992), resulting in considerable saving of energy (Ellison 1995). Less active in the dry season.

Foraging and Food Predominantly granivorous. Eats mostly grass seeds, but also consumes vegetable material and insects.

Social and Reproductive Behaviour Usually solitary, but occasionally pairs occupy a burrow. In Swaziland, mean distance between successive monthly captures was 36.1 m, which suggests a rather sedentary existence (Monadjem 1999b).

Reproduction and Population Structure Reproduction occurs mainly in the wet season. Pregnant and lactating ♀♀ present mostly in Jan–Mar (southern Africa). Recruitment increases in late wet season (mostly Mar–May in Swaziland). Population numbers generally do not vary by more than a factor of two between seasons. Sex ratio does not deviate from parity (Monadjem 1999b).

Predators, Parasites and Diseases Remains collected from pellets of African Grass-owls *Tyto capensis*, Barn Owls *Tyto alba* and Black-shouldered Kites *Elanus caeruleus* (Vernon 1972, Mendelsohn 1982, Smart & Taylor 1990). Widely consumed by humans because of their high fat content. Ectoparasites include three species of mites, nine species of fleas and three species of ticks; some of these ectoparasites are implicated in the transmission of disease to humans and domesticated sheep (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Widespread and common in places. Survives in agricultural landscapes and hence not likely to become threatened.

Subfamily MYSTROMYINAE – White-tailed Rat

Mystromyinae Vorontsov, 1966. Zool. Zh. 45: 437.

The single living genus and species, *Mystromys albicaudatus*, comprising this subfamily is confined to southern Africa, inhabiting the South-West Cape and Zambezian Woodland BZs. The thickset build, simple molars with biserial cusp arrangement, and short tail suggest similarity to the Palearctic hamsters (Cricetidae: Cricetinae) and inspired its less frequently used vernacular name, the Southern African Hamster. Indeed, the genus has been traditionally classified as a lone Afrotropical member of the otherwise Palearctic Cricetinae (Roberts 1951, Ellerman *et al.* 1953, Misonne 1974, De Graaff 1981, Pocock 1987, Skinner & Smithers 1990, Denys 1991). Such a restricted distribution, however, suggests that *Mystromys* is a relict of an older muroid radiation within Africa.

Vorontsov (1966) detailed numerous differences between *Mystromys* and the true hamsters and erected the subfamily Mystromyinae to underscore its morphological uniqueness and probable phylogenetic remoteness. Foremost among those contrasts are the lack of internal cheek pouches (present in Cricetinae), presence of parallel ridges on lower incisors (absent in Cricetinae), mammary glands with only four inguinal nipples (eight or more in Cricetinae), and possession of a hemiglandular stomach with densely papillated corpus (papillae absent in Cricetinae) (Vorontsov 1966, Maddock & Perrin 1983, Pocock 1987). Lavocat (1973, 1978) stressed the genealogical antiquity of *Mystromys*, noting its probable derivation from Miocene cricetodontine rodents, and recognized Mystromyinae as one group among several archaic African muroids within a broadly defined Nesomyidae (also see Carleton

& Musser 1984). The ancestral stock of *Mystromys* has been linked with *Democricetodon*, a cricetodontine from middle Miocene strata of Kenya (Tong & Jaeger 1993), or with *Mioharimys*, a myocricetodontine from the late Miocene of Namibia (Mein *et al.* 2000b).

Recent phylogenetic studies of nuclear and mitochondrial gene sequences reinforce Lavocat's perception of kinship, generally relating *Mystromys* to representatives of Malagasy Nesomyinae and African Cricetomyinae, Dendromurinae and Petromyscinae (Jansa *et al.* 1999, Michaux & Catzeffli 2000, Michaux *et al.* 2001). Analyses of the mitochondrial gene cytochrome *b* indicated *Petromyscus* as the nearest living relative of *Mystromys* (Jansa *et al.* 1999), a relationship supported by the unique development of an elongate medial spine on the ectotympanic bulla in both genera. Other interpretations of its phylogenetic affinity, whether with New World sigmodontine (Ellerman 1941) or gerbilline (Wessels 1996) rodents, find no support from these molecular studies or most morphological characters.

Extinct relatives of *Mystromys albicaudatus* include *M. pocockei* and *Proodontomys cookei*, both well represented by fossils from the Pliocene–Pleistocene australopithecine sites in South Africa (Pocock 1987, Denys 1991, Avery 1998). The distribution of *Mystromys* was once more widespread within the southern African sub-region, as indicated by the presence of mystromyines from the Pleistocene of Namibia (Senut *et al.* 1992).

GENUS *Mystromys* African White-tailed Rat

Mystromys Wagner, 1841. Gelehrte Anz. I. K. Bayer. Akad. Wiss., München, 12 (54), col. 434.

Type species: *Mystromys albipes* Wagner, 1841 (= *Otomys albicaudatus* A. Smith, 1834).

A monotypic genus restricted to South Africa and Lesotho where it lives in savanna grasslands and fynbos habitats. Further details are given in the subfamily and species profiles. The single species is *Mystromys albicaudatus*.

D. C. D. Happold

Mystromys albicaudatus.

Mystromys albicaudatus AFRICAN WHITE-TAILED RAT (SOUTHERN AFRICAN HAMSTER)

Fr. Souris à queue blanche d'Afrique; Ger. Weißschwanzhamster

Mystromys albicaudatus (A. Smith, 1834). S. Afr. Quart. J., ser. 2, 2: 148: 1841, Illustrations of the Zoology of South Africa, Mammalia: pl. 33 and text. Albany District, Eastern Cape Province, South Africa.

Taxonomy Originally described in the genus *Otomys*. The relationships of this species are uncertain (see profile Subfamily Mystromyinae). Synonyms: *albipes*, *antiquus* (probably *nomen nudum*),

fumosus, *hauslichtneri*, *lanuginosa*. Subspecies: none. Chromosome number: not known.

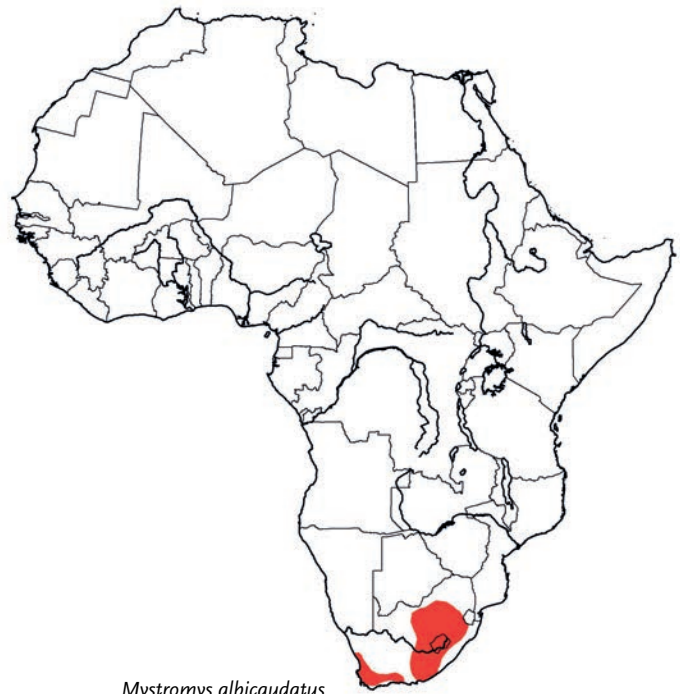

Figure 36. Skull and mandible of *Mystromys albicaudatus* (RMCA 34238).

Description Medium-sized to large, stocky rat with a soft, dense woolly pelage and short white tail. Dorsal pelage greyish-brown, slightly flecked with buff; hairs long (ca. 12 mm), dark grey at base, buff or black at tip. Ventral pelage greyish-white; hairs dark grey at base with off-white or cream tip. Head large and broad, mostly grey. Paler patches above eyes and at back of ears in some individuals. Side of face and upper lips pale grey or white, long vibrissae. Ears darkly pigmented, with dark brown and buff hairs. Fore- and hindlimbs short, off-white. Forefoot with four digits, and dense white hairs on upper surface; hindfoot with five digits, dense white hairs on upper and lateral surfaces; naked on plantar region. All digits with sharp claw. Tail short (ca. 35–40% of HB), unpigmented, with dense short white hairs above and below. Skull: incisors orthodont, zygomatic plate with vertical anterior margin, very long anterior palatal foramina, biserial cusps on molars (Figure 36); see also subfamily profile. Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species No other species of similar weight within the geographic range has such a relatively short tail (ca. 35–40%).

Distribution Endemic to Africa. Highveld and South-West Cape BZs. Recorded in the eastern half of South Africa, south of 25° S (S Mpumalanga, Free State, KwaZulu–Natal and Eastern Cape Provinces) with a relict population in the fynbos of SW Western Cape Province. Also recorded from Lesotho (but not from Swaziland). Probably extended in the past throughout the southern savanna grasslands, heathlands and renosterveld of the SW Cape Province of South Africa. The record of *Mystromys* from Tanzania is incorrect (see Misonne 1974).

Mystromys albicaudatus

Habitat Grasslands, fynbos, montane grasslands, karoo, renosterveld and heathland habitats.

Abundance Uncertain, but probably uncommon or rare. Rarely encountered.

Adaptations Terrestrial and nocturnal. White-tailed Rats live in burrows or in cracks in the soil (De Graaff 1981). They possess a suite of unusual physiological characters: the bilocular hemiglandular stomach has a complex microflora and a ruminant-like digestion (Maddock & Perrin 1981) similar to that of the Gambian Giant Rat *Cricetomys gambianus* (Perrin & Kokkinn 1986); organic acids are produced by the catabolism of complex plant polysaccharides in the foregut and hindgut during digestion; food is fermented by bacteria in the hindgut; and metabolism and thermal regulation are typical of rodents adapted to a cold temperate habitat (Downs & Perrin 1995). The characters of the digestive system are assumed to enable White-tailed Rats to utilize plant foods containing chemical defences, which are unavailable as food to other species. The combination of high metabolic rate (higher than predicted for a mammal of this size), reduction of activity and foraging times in winter, and thermal insulation in burrows, are thought to reduce the necessity for torpor in winter. There is no evidence to suggest that White-tailed Rats enter torpor.

Foraging and Food No data available from wild populations. The special characters of the digestive system (see above) suggest an ability to digest a wide range of predominantly plant foods (Maddock 1981).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Likely to breed throughout the year in the wild (Roberts 1951) but confirmation

is required. Pregnant ♀♀ in the wild recorded in Jan, Jun and Jul. Gestation: 37 days. Litter-size in captivity: 2.9 (1–6). Embryo number: 3 and 4 (n = 2; Rautenbach 1982, Lynch 1983). Weight at birth 6.5 g. Eyes open Day 16–20. Weaned at about Day 38. Young cling to nipples until Day 19 (Hallett & Meester 1971). Minimum age of ♀♀ at first parturition is about six months; litter interval ca. 36 days. Breeds well in captivity.

Predators, Parasites and Diseases Predators include several species of owls (Davis 1959, Dean 1978a). Three species of mites and 12 species of fleas have been recorded (see De Graaff 1981). Susceptible to plague, which occurs sporadically in free-living populations (De Graaff 1981).

Conservation IUCN Category: Endangered. Listed as 'Vulnerable' in the South African Red Data Book (Smithers 1986b).

Habitat loss resulting from agriculture, habitat degradation and encroachment of the Karoo into grasslands are the main reasons for the decline in geographic distribution and populations numbers.

Mike Perrin

Subfamily PETROMYSCINAE – Pygmy Rock Mice

Petromyscinae Roberts, 1951. Mammals of South Africa, p. 434.

This subfamily, consisting only of a single genus (*Petromyscus*) and four species, is endemic to Africa and confined to the South-West Arid BZ. Species of the subfamily live in dry regions where large boulders and rocky outcrops predominate; they are nocturnal, terrestrial and apparently omnivorous.

Rock Mice are small in size, with large pinnae, short limbs and long, soft and silky pelage. The moderately hairy tail is less than, equal to, or moderately longer than head and body depending upon the species. The hindfoot is short and broad, the toes relatively short with Digit 5 nearly as long as Digits 2–4. The cranium exhibits a long and slender rostrum, smooth and broad interorbital constriction, and wide and flat braincase devoid of temporal ridging; the jugal forms a large span of the zygomatic arch, and the zygomatic plate is wide with a deep dorsal notch (Figure 37). Anterior palatal foramina are narrow and long; bony palate wide and long, projecting behind the third molars as a prominent shelf; alisphenoid bone with well-developed dorsal flange and wide ventral strut; subsquamosal foramen closed in adults. The carotid circulatory pattern is partially derived, lacking a supraorbital artery (sphenofrontal foramen and squamosal-alisphenoid groove absent) but retaining the infraorbital (stapedial foramen large); ectotympanic bullae moderately inflated, with medial spine adnate to the basisphenoid. Entepicondylar foramen of humerus present. Stomach unilocular and hemiglandular. The molars are brachyodont and cuspidate, with uppers three-rooted and lowers two-rooted, and their cusps are longitudinally connected by short enamel crests. On M¹ and M² a large lingual cusp is adjacent to the protocone, coalescing with wear; anteroloph(id) and mesoloph(id) absent; discrete posteroloph absent on M¹ and M². M³ is very small, its occlusal pattern C-shaped and unlike that of M². The strongly opisthodont upper incisors have smooth enamel faces.

Figure 37. Skull and mandible of *Petromyscus collinus* (BMNH 25.1.2.154).

Petromyscus was initially considered an aberrant dendromurine because of the extra lingual cusp on its upper molars and the relatively small upper third molar (Allen 1939, Simpson 1945). Roberts (1951), however, diagnosed the subfamily Petromyscinae to stress the unique combination of traits exhibited by the genus and its relict distribution. Subsequent studies have generally reinforced Roberts's perception of phyletic isolation, although interpretations of the nearest generic relatives of *Petromyscus* have varied – whether

a distant kin of *Mystromys* (Ellerman 1941, Roberts 1951), an evolutionary link between *Mystromys* and dendromurines (Lavocat 1964, Petter 1966c), or a sister genus to *Delanymys* (Hayman 1962a, Petter 1967). As diagnostically contrasted above in the account of Delanymyinae, *Petromyscus* and *Delanymys* have little in common aside from the shared lingual molar cusps. Their union in the same subfamily, with the close phylogenetic affinity thereby implied, has been challenged (Carleton & Musser 1984, Denys 1994), and Musser & Carleton (2005) segregated each in its own subfamily. Close relationship of *Petromyscus* and *Mystromys*, on the other hand, has received support from phyletic interpretation of cytochrome *b* data

(Jansa *et al.* 1999), the two genera constituting a clade that is distantly removed from the single dendromurine sampled (*Steatomys*). The derivation of petromyscines has been linked with middle to late Miocene myocricetodontines, around 12–11 mya (Tong & Jaeger 1993, Mein *et al.* 2000b). In particular, Mein *et al.* (2000b) regarded *Harimyscus hoali*, of the late Miocene of Namibia, as the earliest known petromyscine. Namibia today encompasses the greater part of the distribution of three of the four extant species of *Petromyscus*.

Michael D. Carleton & Guy G. Musser

GENUS *Petromyscus*
Pygmy Rock Mice

Petromyscus Thomas, 1926. Ann. Mag. Nat. Hist., ser. 9, 17: 179. Type species: *Praomys collinus* Thomas and Hinton, 1925.

Petromyscus collinus.

The genus *Petromyscus* contains four species (Musser & Carlton 1993, 2005) distributed throughout the South-West Arid BZ (Davis 1962), and is the only genus in the subfamily. The characters of the genus are given in the profile of Subfamily Petromyscinae above. All species in the genus are restricted to rocky habitats where boulders and rocks provide shelter. The four species are distinguished by pelage colour, length of tail and ear, slight differences in skull characters, and geographic distribution (Table 18).

C. G. Coetzee

Table 18. Species in the genus *Petromyscus*. Arranged in increasing head and body length.

| Species | HB mean (range) (mm) | Tail mean (range) (mm) (% of HB) | Nipples | Dorsal pelage | Notes |
|------------------------|----------------------|----------------------------------|-----------|---------------------------|-------------------------------------|
| <i>P. monticularis</i> | 75.3 (63–93) | 73.3 (66–84) (98%) | 1 + 2 = 6 | Dark brown | Namibia, N South Africa |
| <i>P. barbouri</i> | 76 (71–79) | 82 (71–99) (108%) | 0 + 2 = 4 | Drab grey, speckled brown | NW South Africa |
| <i>P. collinus</i> | 79.8 (62–97) | 91 (67–114) (113%) | 1 + 2 = 6 | Buff-brown | SW Angola, Namibia, NW South Africa |
| <i>P. shortridgei</i> | 83.4 (65–98) | 87.4 (74–104) (104%) | 0 + 2 = 4 | Dark brown | S Angola, N Namibia |

Petromyscus barbouri BARBOUR’S PYGMY ROCK MOUSE (NAMAQUA PYGMY ROCK MOUSE)
Fr. Souris des rochers à queue courte; Ger. Barbours Felsenmaus

Petromyscus barbouri Shortridge and Carter, 1938. Ann. S. Afr. Mus. 32: 288. Kamiesberg, Witwater, Little Namaqualand, NW Cape Province, South Africa. 3500–3800 ft (1275–1385 m).

Taxonomy Considered to be a subspecies of *P. collinus* by Smithers (1983) and Meester *et al.* (1986); now recognized as a valid species (Musser & Carleton 1993, 2005). Synonyms: none. Chromosome number: not known.

Description Very small to small mouse, similar in general form to the House Mouse *Mus musculus*. Pelage fine, soft and silky. Dorsal pelage grizzled drab grey, speckled with pale brown. Ventral pelage drab grey. Head similar in colour to dorsal pelage. Juveniles drab

grey without speckled pale brown. Ears relatively large (ca. 83% of HF), darkly pigmented. Fore- and hindfeet relatively short, whitish. Tail long (ca. 108% of HB), bicoloured, drab grey above, white below with sparse bristles especially towards the tip, not forming a pencil or tuft. Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

P. collinus. HB slightly larger; ear longer (mean 15 mm); tail length longer (mean 91 mm) and relatively longer, not bicoloured; longer skull length (mean 25 mm); relatively longer rostrum; sympatric and with much greater geographic range.

P. monticularis. HB similar (mean 75.3 mm); ear shorter (mean 11.6 mm); tail shorter (mean 73.5 mm) and relatively shorter, maybe bicoloured; ear shorter (mean 11.6 mm); allopatric or parapatric; restricted geographic range.

P. shortridgei. HB larger (mean 83.4 mm); ear longer (mean 15 mm); tail slightly longer (mean 87.4 mm), bicoloured; allopatric.

Distribution Endemic to Africa. South-West Arid BZ (Namib Desert and Karoo). Widely distributed in Namaqualand, South Africa (Shortridge & Carter 1938, Shortridge, 1942). In the lower Orange River basin of South Africa, distribution is sympatric or parapatric to that of *P. collinus* and *P. monticularis*.

Habitat Rocky outcrops and hills where there are succulent bushes and annual herbs during the winter rainfall season. Winters wet and cold, summers dry and hot.

Abundance Unknown; regarded as rare.

Remarks Nocturnal. Adapted to arid and semi-arid environment with moist, relatively cold and wet winters and warm, dry summers (Shortridge 1942). Mainly granivorous.

Conservation IUCN Category: Least Concern.

Parts of the range are protected in conservation areas (e.g. Goegab Nature Reserve near Springbok, and Namaqualand National Park). Goat farming could have a harmful and destructive effect on the habitat due to the grazing and browsing of goats amongst the rocks.

Petromyscus collinus PYGMY ROCK MOUSE

Fr. Souris de rochers pygmée; Ger. Zwerg Felsenmaus

Petromyscus collinus (Thomas and Hinton, 1925). Proc. Zool. Soc. Lond. 1925: 237. Karibib, Damaraland, Namibia. 1025 m.

Taxonomy Originally described in the genus *Praomys*. Allocated to the genus *Petromyscus* when that genus was proposed by Thomas in 1926. Synonyms: *bruchus*, *capensis*, *kaokoensis*, *kurzi*, *namibensis*, *rufus*, *variabilis*. Subspecies: none currently recognized but some of the forms listed as synonyms may prove to be valid subspecies. Chromosome number: 2n = 60 (T. Robinson and V. Rambau pers. comm.; Namibia).

Description Very small to small mouse. Pelage soft and silky. Dorsal pelage buff or brown (variable according to locality); hairs dark grey at base, buff or brown at tip. Juveniles dark grey. Ventral pelage white to pale grey; hairs grey at base, whitish at tip. Colours of dorsal and ventral pelage merge on flanks. Head similar in colour to dorsal pelage. Vibrissae long. Ears large (ca. 94% of HF) and rounded, pigmented, sparsely covered with short hairs of the same colour as head. Fore- and hindfeet short, dorsally covered with

short white hair, Digit 5 nearly as long as Digits 2–4. Tail relatively long (ca. 113% of HB), with rings of scales, darker above; may be bicoloured and paler below with sparse short whitish bristles. Skull characters as for genus. Nipples: $1 + 2 = 6$.

Geographic Variation No subspecies recognized but pelage varies in colour forming a cline from darker in the south-east to paler in the north-west.

Similar Species

- P. barbouri*. Slightly smaller body size; tail shorter (and relatively shorter); sympatric in southern part of range; more restricted geographical range.
- P. monticularis*. Smaller body size; dorsal pelage dark brown; tail shorter (and relatively shorter); ear shorter; mean GLS shorter; sympatric in southern part of range; restricted geographical range.
- P. shortridgei*. Larger body size; tail shorter (and relatively shorter); sympatric in central part of range.

Distribution Endemic to Africa. South-West Arid BZ (especially Namib Desert and parts of the Karoo). Recorded from Namibia, desert areas of SW Angola and the Orange River Valley and the central Karoo of South Africa. In Angola, known only west of the Chela Escarpment as far north as $13^{\circ}23'S$, and $13^{\circ}53'E$ (Crawford-Cabral 1998) and where the pro-Namib vegetation reaches the coast at Praia Madalena ($14^{\circ}37'S$, $12^{\circ}18'E$; C. G. Coetzee unpubl.). Widespread in W Namibia in the Namib and adjoining western mountainous regions, southwards to the Orange R. In South Africa, recorded throughout the central Karoo from the border with Namibia to about $33^{\circ}S$ and 19° – $22^{\circ}E$ (J. A. J. Nel unpubl., Stuart *et al.* 1987).

Habitat Arid and semi-arid habitats, especially in mountains and rocky areas where there are crevices amongst large boulders

and rock fringes. Mean annual rainfall 30–400 mm/annum. May also occur along canyons that support some vegetation, and where rainfall is even lower (ca. mean 15 mm/annum).

Abundance Generally rare. May be abundant at some localities, e.g. at Tumasberg, Namibia, where it comprised 65% of six species of small mammals (*Aethomys namaquensis* 21%, *Petromus typicus* 17%, *Elephantulus rupestris* 3%, *Gerbillus paebe* < 1%, *Mus minutoides* < 1%; $n = 239$; Withers 1979). Density on 6 ha study area during most of year was ca. 4–6/ha to 9.5/ha (Withers 1979).

Adaptations Nocturnal. Shelters during daytime in crevices under and amongst rocks and boulders. Emerges at dusk, most active until ca. 02:00h. Not active outside burrows during pre-dawn and early morning (Withers 1979). Broad feet adapted for climbing; limbs short (but capable of vertical jumps of 40 cm; C. G. Coetzee unpubl.). Individuals adjust their water requirements according to water availability. When free water is unavailable, they can survive on water in seeds and other windblown material without the need for drinking water. When water precipitates from fog, water turnover rates increase (Withers *et al.* 1980). Daily energy expenditure is low, and reduced Tb and torpor aid survival in cool weather. The combination of low reproductive potential, low annual mortality and ability to survive on a dry seed diet are advantageous for life in an arid environment. *Petromyscus* appears to be physiologically intermediate between *Petromus typicus* (well adapted) and *Aethomys namaquensis* (less well adapted) in its adaptations to an arid environment (Withers *et al.* 1980). Even so, *Petromyscus* is present in the more xeric regions of the Namib Desert where vegetation is sparse and confined to slight moist areas below or between rocks.

Foraging and Food Granivorous and omnivorous. Foraging for seeds occurs primarily close to the boulders and rocks that provide safety from predators rather than at the base of a kopje or further away (20 and 40 m) on the surrounding alluvial plain (Brown *et al.* 1998). The diet is primarily seeds, with some stems; insects form ca. 25% of stomach contents in the pro-Namib ($n = 16$; Withers 1979). This diet is comparable to that of sympatric *Aethomys namaquensis*, and unlike that of the larger, diurnal *Petromus typicus*, which feeds mainly on plant stems. An alternative source of food on kopjes (where the number of grasses and seeds is limited and hyraxes occur) is seeds deposited in the faecal pellets of hyraxes (which feed extensively away from the kopje), and insects, which themselves are feeding on the faecal pellets (Brown *et al.* 1998). Seeds accumulated amongst and below rocks form an important food source, especially on outcrops and in canyons in extreme xeric regions (C. G. Coetzee unpubl.).

Social and Reproductive Behaviour Solitary. Home-range ca. 0.27 ha (Withers 1979). Home-ranges of ♂♂ show little overlap, but may overlap with those of ♀♀. Home-ranges of ♀♀ often overlap. It is likely that ♂♂ defend their home-ranges against other ♂♂, but tolerate the presence of ♀♀ (Withers 1979). In captivity, fighting occurs between individuals of opposite sex, and ♀ does not tolerate the presence of ♂ (C. G. Coetzee unpubl.).

Reproduction and Population Structure Reproduction is seasonal and ♀♀ probably have 1–2 litters/year. Pregnant ♀♀ and

sexually active ♂♂ recorded Aug–Mar (C. G. Coetzee unpubl.; Namibia). At Tumasberg, Namibia, ♂♂ and ♀♀ become sexually active when fog precipitation begins (Oct–Mar, max Jan–Mar) (Withers 1983). Embryo number: 2.7 (1–6), n = 11 pregnancies (C. G. Coetzee unpubl.). Dempster & Perrin (1989) recorded an average of 2.8 young in eight litters born in captivity. Young are nipple-dragged by mother (Dempster & Perrin 1989). Sex ratio 1:1.27, n = 149 (C. G. Coetzee unpubl.); mean monthly survival 0.9; annual survival rate 0.36; life expectancy 6.6 months (Tumasberg, Namibia; Withers 1979).

Predators, Parasites and Diseases Predators include several species of mammals, owls and snakes (Mammals: *Felis lybica*, *Galerella sanguinea*, *G. pulverulenta*, *Canis mesomelas* and *Vulpes chama*. Owls: *Tyto alba*, *Otus leucotis*, *Glaucidium perlatus* and *Bubo africanus*. Snakes: *Python anchietae*, *Pseudopsis cana*, *Naja nigricollis*, *Naja haje*, *Bitis arietans*, *Bitis cornuta* and *B. caudalis*). Ectoparasites include two species of mites (*Laelaps brandbergensis*, *Androlaelaps zuluensis*) and one species of tick (*Haematophysalis leachii*). Five species of fleas (*Chistopsylla nama*, *Epirimia aganippes*, *Xenopsylla philoxera* [De Meillon *et al.* 1961], *Listropsylla agrippinae* and *Chistopsylla quadrisetis* [Stuart *et al.* 1987]). One species of endoparasite (nematode: *Acanthoxyuris shortridgei*) has been recorded (De Graaff 1981 and references therein).

Conservation IUCN Category: Least Concern.

Protected in several conservation areas such as Iona Park in Angola, Namibia and South Africa.

Petromyscus monticularis BRUKKAROS PYGMY ROCK MOUSE (SHORT-EARED PYGMY ROCK MOUSE)

Fr. Souris des rochers des Monts Brukkaros; Ger. Brukkaros-Felsenmaus

Petromyscus monticularis (Thomas and Hinton, 1925). Proc. Zool. Soc. Lond. 1925: 238.

Small 'kopje' not far from Great Brukkaros Mt, near Berseba, S Namibia. 1100 m. (Type locality correction; Shortridge 1934.)

Taxonomy Originally described in the genus *Praomys*. Synonyms: none. Chromosome number: not known.

Description Very small to small mouse, the smallest species in the genus. Dorsal pelage dark brown; hairs dark grey on basal two-thirds, brown on terminal third. Flanks similar to dorsal pelage. Ventral pelage slate-grey without a clear delineation between dorsal and ventral colouration. Head similar in colour to dorsal pelage. Ear comparatively small (ca. 74% of HF; cf. other congeneric species 83% to 94%), darker than dorsal pelage. Hindfeet with five digits, Digit 5 nearly as long as Digit 2. Fore- and hindfeet whitish dorsally. Tail moderately long (ca. 98% of HB, but comparatively shorter than in other *Petromyscus*); slightly scaly, dark brown above, same colour or slightly paler below, sparsely covered with hairs. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

P. barbouri. Slightly larger body size, tail slightly longer, ears larger, diastema shorter in relation to upper molar tooththrow; probably parapatric in South Africa.

P. collinus. Slightly larger body size; dorsal pelage brown; tail longer (and relatively longer); ears larger (and relatively larger); sympatric throughout most of range; more extensive geographic range.

Aethomys namaquensis (young). Similar size (adults much larger); tail and hindfoot relatively longer.

Petromyscus monticularis

Mus indutus. Smaller body size; ventral pelage pure white, clearly delineated from dorsal pelage.

Distribution Endemic to Africa. South-West Arid BZ (mainly southern part of Namib Desert). Recorded only in Namibia and South Africa from the edge of the Namib Desert in the west (roughly between 25–26° S and 16–18° 30' E) south-eastwards into the arid Karoo to about 30° S and 21° E. Range extends upstream along the Orange R. catchment to below its junction with the Vaal R.

Habitat Rocky plains, mostly amongst small stones and rock rubble at the foot of rocky outcrops; does not live amongst large boulders on mountain slopes. Habitat is mostly Dwarf Shrub Savanna in Namibia (Giess 1971), and the Karoo in South Africa. Sympatric (and probably syntopic) with *P. collinus*.

Abundance Rare.

Remarks Mainly granivorous, and omnivorous. Stomach contents (n = 17) contained seeds (100% of stomachs), insects (53%) and plant remains (37%). In Feb, all individuals were adult: ♂♂ scrotal; ♀♀ not pregnant (Baker & Baker 1984). Grass seeds blowing in from the plains and accumulating amongst stones are an additional source of food, apart from the plants growing locally.

Conservation IUCN Category: Least Concern.

Habitat conservation is important for survival of the species. Habitat disturbance by domestic sheep and goats could be a problem, especially during periods of prolonged drought. Protected in the Fish River Canyon N. P. in Namibia, in the Augrabies N. P. in South Africa, and in private parks and conservation areas.

Petromyscus shortridgei SHORTRIDGE'S PYGMY ROCK MOUSE (KAOKOVELD PYGMY ROCK MOUSE)

Fr. Souris des rochers de Shortridge; Ger. Shortridges Felsenmaus

Petromyscus shortridgei Thomas, 1926. Proc. Zool. Soc. Lond. 1926: 306. Rua Cana Falls (= Cunene Falls), S Namibia. 877 m.

Taxonomy Originally described as a species by Thomas (1926), but considered to be a subspecies of *P. bruchus* (now a synonym of *P. collinus*) by Roberts (1951) or a subspecies of *P. collinus* (Ellerman *et al.* 1953, De Graaff 1981, Meester *et al.* 1986). Currently considered to be a valid species (Musser & Carleton 1993, 2005). Synonyms: none. Chromosome number: not known.

Description Very small to small mouse, although on average larger than other species in the genus. Pelage soft. Dorsal pelage dark brown, finely speckled with brownish-black; hairs dark grey on basal two-thirds, brown on terminal third. Ventral pelage greyish-white; hairs slate-grey at base, white at tip. Dorsal pelage in young and subadults greyish. Ears large (ca. 91% of HF), round. Fore- and hindfeet dorsally whitish. Hindfeet with five digits; Digit 1 reduced, Digit 5 nearly as long as Digit 2. Tail moderately long (ca. 104% of HB), bicoloured, dark brown above, cream below, bristles short. Nipples: 0 + 2 = 4 (sometimes ?1 + 2 = 6).

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

P. collinus. Slightly larger; tail longer (and relatively longer); sympatric; larger geographical range (other *Petromyscus* spp. are allopatric to *P. shortridgei*).

Aethomys namaquensis (young). Similar size (adults much larger); tail and hindfoot relatively longer.

Petromyscus shortridgei

Mastomys coucha (subadult). Similar size (adults larger); dorsal pelage grey; Digit 5 of hindfoot not lengthened.

Distribution Endemic to South-West Arid BZ (northern part of the Kalahari Desert and Namib Desert) and adjoining parts of Zambezian Woodland BZ. Recorded from Angola and Namibia. In SW Angola, occurs in mountainous areas in semi-arid regions (Crawford-Cabral 1998), and in the Cunene River Valley below the Cunene Falls. In Namibia, occurs in the Kaokoveld north of ca. 22° S, and eastwards throughout the Karstveld towards the Otavi and Waterberg Mts.

Habitat Hilly mountainous country. Preferred habitat is rugged granitic mountainous areas (interspersed with dolomites and igneous complexes); here loose boulders are piled on top of each other, providing holes and crevices, and common trees are *Kirkia acuminata*, *Croton* spp. and *Commiphora* spp.

Abundance Generally rare, relatively more abundant than other rodents in extreme xeric areas, and in some localities may be the only species.

Remarks Nocturnal, solitary. Legs and feet short, well adapted for climbing and moving around boulders. Diet consists mainly of seeds but also insects, stems and leaves. Pregnant ♀♀ were collected during Feb, May and Aug–Nov. Embryo number: 2–4 (n = 16; Shortridge 1934, C. G. Coetzee unpubl.).

Conservation IUCN Category: Least Concern.

The habitat is currently not threatened because of the ruggedness of the terrain and low impact of human activities.

Family CRICETIDAE

HAMSTERS, VOLES AND NEW WORLD MICE AND RATS

Cricetidae Fischer de Waldheim, 1817. Mém. Soc. Imp. Nat., Moscow 5: 372.

| | | |
|-------------------------------|---------------|--------|
| <i>Microtus</i> (1 species) | Muster's Vole | p. 211 |
| <i>Lophiomyys</i> (1 species) | Maned Rat | p. 213 |

The family Cricetidae, embracing some 130 genera and over 670 species (Musser & Carleton 2005), represents one of the two dominant radiations of living muroid rodents. Species in the family are abundant in many terrestrial habitats in the New World (Neotominae and Sigmodontinae), Holarctic (Arvicolinae) and Palearctic (Cricetinae), but only two species with restricted distributions are present in Africa (one Arvicolinae in coastal regions of North Africa, and one Lophiomyinae in East Africa). Members of Arvicolinae and Lophiomyinae are so morphologically distinctive (see subfamily and species profiles below) that their separation is unmistakable, whether from one another or from any African species of Spalacidae, Nesomyidae or Muridae. Although possessing numerous derived traits, Arvicolinae and Lophiomyinae have molars whose cusps are arranged biserially and connected medially by longitudinal enamel crests, dental characters thought to be primitive for the family and indicative of their descent from some very distant common ancestor.

The recognition of a family Cricetidae, notably as distinct from a comparably speciose Muridae, has long and recurrent support in influential classifications of muroid rodents (e.g. Miller & Gidley 1918, Simpson 1945, Misonne 1974, Chaline *et al.* 1977, Reig 1984). The contents and rank of muroid groups apportioned among the two families have differed in detail (see summary in Carleton & Musser 1984); indeed, some authorities have recognized only a single, all-inclusive family Muridae that includes all those groups others have classified under Cricetidae (Thomas 1897, Ellerman 1941, Carleton & Musser 1984). Monophyly of the family, as understood here, finds general support in recent phylogenetic evaluations of gene-sequence data (Robinson *et al.* 1997, Dubois *et al.* 1999, Michaux & Catzeflis

2000, Michaux *et al.* 2001). This cladistic view of Cricetidae, in particular the inclusion of Lophiomyinae, requires extended phylogenetic investigation.

Within Africa, the Lophiomyinae is known from the late Miocene to Pleistocene in Morocco and Recent in East Africa (Aguilar & Michaux 1989–1990, Geraads 1998), and Arvicolinae from the middle Pleistocene to Recent in Mediterranean Africa (Jaeger 1988b). The fossil record of ‘cricetids’ in North America and Eurasia is more taxonomically diverse and geologically older (late Eocene to Recent; McKenna & Bell 1997), and several groups, e.g. cricetodontines, eucricetodontines, paracricetodontines and cricetomines, have been variously acknowledged as families separate from Cricetidae. In fact, certain African Miocene genera, such as *Afrocricetodon* and *Myocricetodon*, had been affiliated previously within a broadly defined Cricetodontinae in the family Cricetidae. The gist of current understanding, however, indicates that the latter genera, and their subsequently described relatives, have figured prominently in the evolutionary origin of other muroid assemblages concentrated in Africa (*Afrocricetodontinae* and *Nesomyidae*; *Myocricetodontinae* and *Gerbillinae*). The specifics of such ancestral-descendant connections, and their classificatory representation, are subject to dispute among palaeontologists, and new fossil discoveries from critical middle Tertiary beds continue to emerge and revise considerations of affinity. The reader is referred to Lavocat (1978), Tong & Jaeger (1993) and Mein *et al.* (2000b) for overviews of many of these extinct African groups.

In Africa, the family is represented by two subfamilies, Arvicolinae and Lophiomyinae, each with a single species. Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

Michael D. Carleton & Guy G. Musser

Subfamily ARVICOLINAE – Voles, Lemmings and Muskrats

Arvicolinae Gray, 1821. London Med. Repos. 15: 303.

This large Holarctic subfamily, numbering about 28 genera and 153 species worldwide (Musser & Carleton 2005), has only one representative (*Microtus mustersi*) in Africa. The members of this subfamily form an important component of ecological communities in temperate, boreal and arctic biomes throughout much of the northern hemisphere. In Asia and North America, a few species occupy montane tropical forests and sub-alpine parklands south of the Tropic of Cancer (22°S), whereas in Africa, the southern limit is about 30°N on the Mediterranean littoral of northern Libya. Climatic conditions along Africa’s Mediterranean littoral ameliorated periodically during the Pleistocene and Holocene, allowing voles to reach northern Africa from the Middle East. However, the present distribution of the subfamily in Africa is severely restricted by the arid environment of the Sahara Desert. Other voles, such as *Ellobius*, once occurred broadly over northern Africa during the middle to

late Pleistocene (Jaeger 1988a), extending as far west as Morocco; today, the nearest approach of this genus to Africa lies in eastern Turkey and north-western Iran.

Within the Arvicolinae, *M. mustersi* is a member of a highly derived genus, *Microtus* (63 species), and tribe, Arvicolini (ten genera), whose worldwide ranges are practically congruent with that of the subfamily. Monophyly of the genus is supported by chromosomal, allozymic and DNA studies (e.g. Chaline & Graf 1988, Zagorodnyuk 1990, Modi 1996, Conroy & Cook 2000). Many apomorphic morphological traits also characterize species of *Microtus* (see review by Carleton 1985): noteworthy are the possession of continuously growing (rootless) molars, cement in the re-entrant angles, increased number of molar prisms and subtle rearrangements of the enamel microstructure (Hinton 1926a, Guthrie 1971, Phillips & Oxberry 1972, von Koenigswald 1980). Such evolutionary

innovations, accompanied by architectural restructuring of the cranium and zygomatic musculature (Kesner 1980), served to enhance side-to-side chewing, comminution of abrasive foods such as siliceous forbs and grasses, and exploitation of a herbivorous niche, the trophic hallmark of the subfamily. *Microtus* is known from the late Pliocene to Recent (Repenning 1992, Chaline *et al.* 1999), but the major episode of specific radiation did not transpire until the middle

Pleistocene, about 1.3 mya (Conroy & Cook 2000). The geological range of Arvicolinae is early Pliocene to Recent in Eurasia and North America, and middle Pleistocene to Recent in Mediterranean Africa (Jaeger 1988, McKenna & Bell 1997).

Michael D. Carleton & Guy G. Musser

GENUS *Microtus*

Voles

Microtus Schrank, 1798. Fauna Boica 1: 72. Type species: *Microtus terrestris* Schrank, 1798 (= *Mus arvalis* Pallas, 1778).

The genus is widespread in the Palearctic region and is represented by only a single species (*Microtus mustersi*) in Africa. The characters of the genus are given in the profile Subfamily Arvicolinae and the species profile below.

D. C. D. Happold

Microtus mustersi MUSTERS'S VOLE

Fr. Campagnol de Musters; Ger. Musters Wühlmaus

Microtus mustersi Hinton, 1926. Merg, Cyrenaica, Libya. Ann. Mag. Nat. Hist., ser. 4, 18: 305.

Taxonomy The status of *mustersi* is debatable. Ranck (1968) considered *mustersi* as a species distinct from other species of *Microtus* in the Middle East, i.e. *M. philistinus*, *M. guentheri* and *M. irani*. In contrast, Musser & Carleton (1993) place *mustersi* as a synonym of *Microtus irani*, and Ellerman & Morrison-Scott (1951) and Musser & Carleton (2005) place it as a subspecies of *M. guentheri*. However, the Libyan population of *Microtus* is isolated from all other populations; the next nearest form (*philistinus* = *M. guentheri*) is in Israel about 1200 km to the east. Because of its isolation, as well as differences in skull morphology and colour from other members of the genus, *mustersi* is retained as a species here. Synonyms: none. Chromosome number: not known.

Description Small brown vole with soft pelage and short tail. Dorsal pelage medium-brown; dorsal hairs soft, dense and fairly short, dark grey with medium-brown tips. Pelage paler on flanks, merging into whitish-grey on ventral surface. Ventral hairs shorter than dorsal hairs, grey with creamy-white tips. Ears small and rounded, covered with short brown hairs, and partially covered by hairs on cheeks. Chin, throat and chest grey. Fore- and hindlimbs with creamy-white hairs. Tail very short (ca. 25% of HB) and thin, covered with short brown hairs above, white hairs below. Skull: incisors orthodont, ungrooved; zygomatic plate small and convex, not extending anteriorly to zygomatic arch; zygomatic arches smooth and wide; auditory bullae moderately inflated; cheekteeth with very characteristic 'zig-zag' pattern of enamel and dentine; M¹, M² and M³ almost of equal length, each with three labial outward-pointing cusps (Figure 38). Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Figure 38. Skull and mandible of *Microtus mustersi* (BMNH 26.8.4.3).

Similar Species This is the only species of vole in Africa. Distinguished from other species of rodents in Libya by its shaggy pelage, small hairy ears and very short tail.

Distribution Endemic to Africa. Sahara Arid BZ. Recorded only on the Cyrenaica Plateau and coastal plains of N Libya. It seems likely that voles reached Cyreniaca from coastal Egypt (Ranck 1968), and that the present population is a relict from the time when the more boreal climates of the Pleistocene prevailed over North Africa. The Cyrenaica Plateau by virtue of its higher elevation has retained at least a vestige of these boreal elements, whereas the remainder of coastal Africa has become much drier and more sparsely vegetated and no longer contains habitats suitable for voles (Ranck 1968).

Habitat On the coastal plain, Musters's Voles live in dense cover of bush-like perennials, together with *Mus musculus* (*Mus spretus*), *Gerbillus campestris* and *Crocidura russula* (Ranck 1968), and rarely occur in tamarix, grass and sedge habitats (Ranck 1968). Also found in agricultural fields and areas where there is surface water in winter and spring. At higher elevations on the Cyrenaica Plateau, they live among large rocks and succulent vegetation (Hufnagl 1972).

Abundance 'Common' near the town of Merg (Hinton 1926b) where the type series was collected. In Lebanon, population numbers

of related species of voles fluctuate dramatically from year to year, and they may be serious agricultural pests when populations are high (Lewis *et al.* 1967, Atallah 1978).

Adaptations Voles (*Microtus* spp.) breed rapidly (see below) and hence their population numbers may increase very rapidly. Like voles in Europe, Musters's Voles dig burrows and make runs through dense vegetation. They appear to be active at most hours of the day and night.

Foraging and Food Herbivorous. Stalks of grasses are pulled into the burrows (J. L. Chaworth-Musters in Hinton 1926b).

Social and Reproductive Behaviour Live in groups in large burrows. Well-marked runways link burrow systems. There is some evidence that ♂♂ and ♀♀ live in different burrows during the breeding season (J. L. Chaworth-Musters in Hinton 1926b).

Reproduction and Population Structure No information. Related species in Lebanon are very prolific and breed throughout the year at lower altitudes; such ♀♀ produce an average of 8 embryos/litter ($n = 27$ ♀♀) and consequently when populations are increasing rapidly, they are comprised mainly of young animals (Atallah 1978).

Predators, Parasites and Diseases Preyed on by Barn Owls *Tyto alba* (specimens in SMF). Owls, hawks, foxes, mustelids and snakes prey on related species of voles in Israel (Qumsiyeh 1996).

Conservation IUCN Category: Least Concern (as *M. guentheri*). However, status of *M. mustersi* in Libya is poorly known; the populations are isolated and have a small geographic range.

Subfamily LOPHIOMYINAE – Maned Rat

Lophiomyinae Milne-Edwards, 1867. Arch. Mus. Hist. Nat. Paris. Memoires C, III: 81–116.

The geographic range of the single living genus and species comprising this subfamily is confined to eastern Africa. Within this region, the recorded distribution of *Lophiomyys imhausi* is disjunct and its altitudinal range is exceptionally broad, from sea level to over 3000 m; habitat

associations are correspondingly varied, including dry lowland woods and montane forest, rocky ravines and brush-covered banks (Hollister 1919, Kingdon 1974, Clausnitzer & Kityo 2001, Pearch *et al.* 2001). Eleventh-century archaeological records of the species from the

Judean Desert, Israel (Dor 1966) may represent human transport, and suppositions about a former natural range in Arabia (Kingdon 1991) are so far unsubstantiated (Kock & Künzel 1999). Abundant palaeontological evidence, however, documents the prehistorically wider occurrence of the subfamily in Africa, southern Europe and perhaps south-western Asia. The genus is known, as *Lophiomys maroccanus* or species indeterminate, from the late Miocene to Pleistocene of Morocco (Aguilar & Michaux 1989–1990, Geraads 1998). Further, *Protolophiomys* of the late Miocene in Spain (Aguilar & Thaler 1987) bears certain cranial and dental traits that warrant its membership in Lophiomyinae, while the subfamily allocation of *Microlophiomys*, described from isolated molars in late Miocene sediments in Ukraine (Topachevsky & Skorik 1984), remains open to question.

Lophiomys is very large in size and boldly coloured in black and white, such that its superficial appearance is non-muroid and even non-rodent. The colour patterning, exaggerated by an erectile dorsal crest flanked by the white-accented glandular tracts, suggests an aposematic function and has evoked comparisons with the zorilla, a small porcupine, opossum, or even the Malayan gymnure. While the strongly cuspidate molars of *Lophiomys* recall a large *Cricetus* (Cricetinae), the pebbled, dermal roofing of the skull is unique among the 1500 species of living Muroidea. Granulated extensions of the frontal, parietal, squamosal and jugal bones completely roof the temporal and much of the orbital fossae, perhaps functioning to deflect predatory attacks and protect the eyes, masticatory muscles and brain. Among the many other distinctive morphological traits of *Lophiomys* are the oval shape of the infraorbital foramen ('keyhole' shape in most muroids), absence of a horizontal plate of the parapterygoid fossa and accompanying foramen ovale accessorius (present in nearly all others), vertebral column with 16 thoracic and seven lumbar vertebrae (13 thoracic and six lumbar are typical), and the much reduced clavicles not contacting the scapulae and sternum (articulation with both elements is typical) (Tullberg 1899, Carleton & Musser 1984).

Lophiomys imhausi is apparently the only species among Muroidea whose stomach is highly compartmentalized. The stomach in most muroid species is single chambered, less commonly dual chambered in certain cricetids and murids (Vorontsov 1967, Carleton 1973, Perrin & Curtis 1980, Musser & Durden 2002). That of *Lophiomys*, however, contains five anatomically discrete sections that superficially resemble the sacculated configuration characteristic of ruminant artiodactyls (Vorontsov 1967). Studies of gastric histology, physiology and digestion would be extremely informative in relation to the animal's diet and ecological niche. By virtue of its large size and biomass, *Lophiomys* may be one of the few muroid rodents that can harbour a symbiotic microflora in the foregut and profit metabolically from gastric fermentation of cellulose. In contrast, hindgut fermentation (large intestine and caecum), in contrast to foregut (stomach) fermentation, is the nutritional process characteristic of muroid species.

The uniqueness and highly derived condition of such morphological adaptations are reflected in the taxonomic isolation of *Lophiomys imhausi*, typically classified as a monotypic family of Muroidea (Tullberg 1899, Ellerman, 1941) or subfamily of Cricetidae (Miller & Gidley 1918, Simpson, 1945, Chaline *et al.* 1977). Lavocat (1973, 1978), on the other hand, regarded *Lophiomys* as a derivative from the Miocene Afrocricetodontinae and arranged Lophiomyinae within a broadly defined Nesomyidae. The molars of extant *Lophiomys* are complex (Wahlert 1984), but occlusal patterns are less complicated in extinct forms and more closely resemble those of Miocene Cricetidae such as *Megacricetodon* and *Democricetodon*. The latter genus first appears in early Miocene sediments of Europe and has now been documented in the middle Miocene of East Africa, leading Tong & Jaeger (1993) to speculate that it represents the African ancestor of *Lophiomys*. Although Lophiomyinae is here associated within Cricetidae, the several interpretations of its relationship have yet to be rigorously investigated in a phylogenetic context.

Michael D. Carleton & Guy G. Musser

GENUS *Lophiomys*

Maned Rat

Lophiomys Milne-Edwards, 1867. L'Institut, Paris 35: 46. Type species: *Lophiomys imhausi* Milne-Edwards, 1867.

Lophiomys is a monotypic genus distributed in eastern Africa. The characters of the genus are given in the subfamily and species profiles.

LEFT AND BELOW: *Lophiomys imhausi*.

Lophiomyys imhausi MANED RAT (CRESTED RAT)

Fr. Rat à crinière; Ger. Mähnenratte

Lophiomyys imhausi Milne-Edwards, 1867. L'Institut, Paris 35: 36.

'Probably from the African coast opposite Aden, where it was purchased' (= Somalia).

Figure 39. Skull and mandible of *Lophiomyys imhausi* (BMNH 73.1756).*Lophiomyys imhausi*

Taxonomy Thomas (1910c) recognized four species of *Lophiomyys* in East Africa; all are now considered to represent a single species. Synonyms: *aethiopicus*, *bozasi*, *hinde*, *ibeanus*, *smithi*, *testudo*, *thomasi*. Subspecies: none. Chromosome number: not known.

Description Very large rat with thick shaggy black and white pelage and bushy tail. Dorsal pelage long and thick, mainly black, flecked with white. Guard hairs long and coarse (up to 65 mm in length); mostly black, some with white tip, some with white band near base. Underfur thick, shorter than guard hairs (ca. 30 mm), grey at base, white on terminal half; underfur mostly visible through guard hairs. Pelage when parted has four bands of colour: grey at base, then white, black and white. Long hairs on back, from top of head to base of tail, form thick white-tipped crest (or mane), which may be erected when animal is frightened. Flanks similar to dorsal pelage with longitudinal band of short brown or cinnamon hairs, broad anteriorly and becoming narrow posteriorly, from behind head to rump. Ventral pelage greyish; hairs 10–15 mm, pale grey to pale buff, with white tips. Head blackish-brown on muzzle, cheeks and around eyes (see also Geographic Variation). Ears smallish, rounded, with short blackish-brown hairs on surface and white hairs around outer margins. Fore- and hindlimbs black and shortish. Forefeet large; Digit 1 without claw, Digits 2–5 with well-developed claw. Hindfeet broad; Digits 1–5 with claw. Tail moderately long (80% of HB), well covered with long shaggy hair; hairs mostly black with white at tip. Skull is massive and strongly built; dorsal surface covered with small bony projections, which results in a 'pebbled' effect (Figure 39); see also subfamily profile, and below. Dental formula: $I\ 1/1, C\ 0/0, P\ 0/0, M\ 3/3 = 16$. Nipples: not known. See also subfamily profile.

Geographic Variation Considerable variation in the number of white-tipped hairs (and hence the 'whiteness' of the pelage). Individuals from Djibouti have a broad whitish line on the forehead, which extends backwards above each eye to base of each ear, and a white tip to the tail (Kock & Künzel 1999).

Similar Species No other rodent has such long shaggy black pelage and distinctive markings, nor a skull with a 'pebbled' structure on the dorsal surface. Rodents of similar size are: *Cricetomys gambianus*: short pelage, naked tail, black at base, white at tip, cheekteeth $3/3$. Squirrels: short pelage, long bushy tail, agile, arboreal (except *Xerus*), cheekteeth $4/4$.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ and scattered localities in Afroalpine–Afroalpine BZ of eastern Africa. Recorded from E Sudan (Red Sea Hills), Eritrea, Ethiopia, Djibouti, Somalia, Kenya, Uganda (and W Tanzania) (Kock & Künzel 1999). Although the species is said to occur in Saudi Arabia (Kingdon 1991), its occurrence at the present time is unlikely (Harrison & Bates 1991, Kock & Künzel 1999).

Lophiomys imhausi.

Habitat Moist and montane forests in Kenya, but drier woodlands and rocky areas elsewhere. In Ethiopia, occurs from sea level to 3300 m.

Abundance Uncertain; rarely seen. Probably rare or uncommon.

Adaptations Nocturnal, semi-arboreal and slow-moving. At night, Maned Rats scramble over undergrowth and tree trunks, and climb trees. During day they hide in hollow tree trunks or in holes located on the edge of ravines or in bushy banks (Kingdon 1974). Aggressive; when an individual is disturbed or frightened, it hisses, growls, snorts or barks, and erects the crest of hairs on the back. The skull is unique amongst mammals: it is solidly built, the upper surface is strengthened with many small circular bony projections (0.3 mm across, and 0.3 mm between projections), and the parietal bones have lateral extensions that join with the zygomatic arch posterior to the orbit providing extra protection to the braincase.

Foraging and Food Herbivorous; feeds on leaves and tender shoots. The stomach has several compartments, and symbiotic fauna in the stomach are thought to assist in the digestion of food (see subfamily profile).

Social and Reproductive Behaviour Little information; usually seen singly.

Reproduction and Population Structure Litter-size: 1–3. Young slightly haired at birth. White markings and black stripes on

body visible by Day 9. Eyes open by Day 13. Hair sufficiently long that crest is erectile by Day 20. Mobile by Day 23. Weaned by Day 40 (Delany 1975).

Parasites, Predators and Diseases Ectoparasites include plague fleas (Kingdon 1974).

Conservation IUCN Category: Least Concern.

Conservation status is uncertain because individuals are rarely seen.

Family MURIDAE
GERBILS, JIRDS, RATS AND MICE

Muridae Illiger, 1811. Abhandl. K. Akad. Wiss. Berlin for 1804–11, p. 46, 129.

| | | |
|-------------------------------------|---|--------|
| Deomyinae (4 genera, 30 species) | Spiny Mice, Link Rat and Brush-furred Rats and Mice | p. 217 |
| Gerbillinae (12 genera, 71 species) | Gerbils, Jirds | p. 260 |
| Leimacomyinae (1 genus, 1 species) | Buettner's Togo Mouse | p. 358 |
| Murinae (31 genera, 145 species) | Old World Rats and Mice | p. 361 |
| Otomyinae (2 genera, 17 species) | Vlei Rats | p. 571 |

The Muridae, the largest of the several families of Muroidea, is indigenous to the Old World, originally distributed throughout most of Eurasia, Africa (except Madagascar) and the Indo-Australian region. Currently, 150 genera and 730 species are recognized worldwide (Musser & Carleton 2005); of these, Africa contains five subfamilies, 50 genera and 264 species (as listed above; see also order profile). Certain commensal species of the subfamily Murinae opportunistically accompanied the Holocene meanderings of humans, spread far beyond their natural ranges, and now occur nearly worldwide. The family is abundantly represented throughout Africa, where two (Leimacomyinae, Otomyinae) of the five subfamilies are geographically restricted and where the others (Deomyinae, Gerbillinae, Murinae) are represented by taxonomically diverse, moderately to highly speciose radiations that are geographically widespread. All of Africa's biotic zones contain at least some members of the family, and species of Muridae typically comprise a substantial proportion of the numbers of individuals and biomass in most terrestrial small mammal communities. African murids range in size from about 5 g to 210 g, are mostly terrestrial and nocturnal, occupy numerous natural and anthropogenic habitats, and are well represented in herbivorous (many Murinae, Otomyinae), granivorous (Gerbillinae) and insectivorous and carnivorous trophic guilds (Deomyinae, Leimacomyinae, some Murinae).

The family has been conceived with a broad or narrow taxonomic meaning in the superfamily Muroidea. In the broad sense, Muridae was thought to contain most muroid groups, either excluding (Thomas 1897, Ellerman 1941) or including (McKenna & Bell 1997) the fossorially specialized Spalacidae and (non-African) Rhizomyidae. In the narrow sense, Muridae was separated from a comparably large and systematically diverse Cricetidae (and variously other families), in addition to the fossorial families (Tullberg 1899, Miller & Gidley 1918, Simpson 1945). Reduction or loss of longitudinal enamel crests on the molars (crests standardly found in Cricetinae) is a cardinal derived trait for postulating a sister-group relationship between Gerbillinae and Murinae (Flynn *et al.* 1985, Tong & Jaeger 1993), which together form the core of Muridae. The phyletic union of these and other subfamily members, as presented herein, draws convincing support from recent gene-sequencing studies, which collectively identify deomyines, gerbillines, murines and otomyines

(Leimacomyinae not yet sampled) as comprising a major lineage within Muroidea (Hänni *et al.* 1995, Robinson *et al.* 1997, Dubois *et al.* 1999, Martin *et al.* 2000, Michaux *et al.* 2001, Jansa & Weksler 2004). This large clade (Muridae) is hierarchically delineated from others that contain representative species of Spalacidae, Cricetidae and Nesomyidae (see family and subfamily profiles for additional discussion).

A consensus accepts *Antemus*, known from the middle Miocene of Pakistan, as the oldest-known murid, one believed to represent a stem member in the initial radiation of the family (Jacobs 1977, Flynn *et al.* 1985, Jacobs *et al.* 1990, Jacobs & Downs 1994, Freudenthal & Martín Suárez 1999). Earliest members of Muridae so far documented in Africa appear shortly thereafter in the late Miocene: *Preacomys* (Deomyinae) in Ethiopia (Geraads 2001), *Protatera* (Gerbillinae) in Morocco (Jaeger 1977b), *Paraethomys* and *Progonomys* (Murinae) in North Africa (Jaeger 1977b, Mein *et al.* 1993), *Karnimata* and *Saidomys* (Murinae) in Kenya (Winkler 2001) and *Euryotomys* (Otomyinae) in South Africa (Sénégal & Avery 1998). Myocricetodontines, a complex and widely distributed Neogene group (early Miocene–early Pliocene of Africa, Europe and southern Asia), are variously implicated in the origin of the two dominant murid subfamilies, Gerbillinae and Murinae (Tong 1989, Tong & Jaeger 1993, Lindsay 1994, Wessels 1996, 1999, Winkler 2002).

In view of this fossil record and palaeo-distribution, authors have routinely identified southern Asia as the evolutionary source of African Muridae (or specifically Murinae). Two or more immigrations in the middle Miocene to late Miocene–Pliocene are thought to account for the continent's present diversity and taxonomic composition (Jacobs 1985, Winkler 1994, 2002). Tong & Jaeger (1993), on the other hand, suggested an African origin of murids. Such speculations about evolutionary origin and intercontinental migration have a precarious foundation because new fossil sites in north-eastern Africa and the Arabian Peninsula continue to be discovered and the taxonomy of their rodent faunas still requires synthesis (Flynn & Jacobs 1999, Geraads 2001, Winkler 2001, 2002). In regard to the suggestion of Tong & Jaeger, it is instructive to note that two of the five murid subfamilies (Leimacomyinae, Otomyinae) are endemic to Africa, that the taxonomic diversity of two others (Deomyinae, Gerbillinae) is today strongly concentrated within the continent (and in the case of Gerbillinae, the earliest diverging clades are sub-Saharan), and that the fifth (Murinae) contains a large, possibly monophyletic group that radiated extensively within sub-Saharan biotopes. If Africa is not the area of origination of Muridae, its landscapes have none the less played a prominent role in the family's diversification.

Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

Michael D. Carleton & Guy G. Musser

Subfamily DEOMYINAE – Spiny Mice, Link Rat and Brush-furred Rats

Deomyinae Thomas, 1888. Proc. Zool. Soc. Lond. 1888: 132.

| | | |
|--------------------------------|--------------------|--------|
| <i>Acomys</i> (13 species) | Spiny Mice | p. 217 |
| <i>Deomys</i> (1 species) | Link Rat | p. 235 |
| <i>Lophuromys</i> (15 species) | Brush-furred Rats | p. 238 |
| <i>Uranomys</i> (1 species) | Brush-furred Mouse | p. 258 |

Deomyinae is a small subfamily that comprises only four genera (*Acomys*, *Deomys*, *Lophuromys* and *Uranomys*) and 30 species, whose specific and generic diversity is concentrated in sub-Saharan Africa. The genus *Acomys*, however, is also represented in North Africa, the Mediterranean islands of Cyprus and Crete, and the Middle East and Asia Minor. Deomyines are very small to medium in size, with hispid to spiny pelage, and each genus is highly distinctive in morphology. All species are terrestrial, mostly nocturnal, and primarily insectivorous, although some species of *Acomys* may consume substantial amounts of vegetable food.

The aggregation of these four genera into a distinctive murid subfamily appears anomalous when one considers their early classificatory history. In the case of *Acomys*, *Lophuromys* and *Uranomys*, systematists had noted their close relationship, especially similarities of pelage texture, palatal configuration and molar patterns, but continued to arrange them within the Murinae (Ellerman 1941, Misonne 1969a, Rosevear 1969), perhaps as an early offshoot based on retention of a discrete t3 on M³ (Denys & Michaux 1992, Denys *et al.* 1992). Monophyletic unity of these three genera has been sustained by subsequent morphological and molecular studies, and this evidence has prompted both a reconsideration of their antiquity relative to Murinae proper and possible kinship to Gerbillinae (Sarich 1985, Chevret *et al.* 1993b, Breed 1995, Hänni *et al.* 1995, Watts & Baverstock 1995a, Dubois *et al.* 1999).

In the case of *Deomys*, no special relationship to the above three genera, or even to Murinae, was appreciated. In fact, the genus was isolated in its own subfamily Deomyinae (Thomas 1888, Ellerman 1941) or reservedly grouped within a polyphyletic Dendromurinae (Rosevear 1969, Carleton & Musser 1984). A fresh perspective has emerged from recent sequence studies of mitochondrial and nuclear genes, which consistently support close relationship between *Deomys*

and *Acomys-Lophuromys-Uranomys*, in various combinations depending upon the study, and underscore the early divergence of the clade Deomyinae-Gerbillinae relative to Murinae (E. Verheyen *et al.* 1996, Michaux & Catzeflis 2000, Michaux *et al.* 2001, Chevret *et al.* 2001, Jansa & Weksler 2004). Cladistic analysis of morphological traits, primarily dental ones, has not disclosed a clade consisting of *Deomys* and *Acomys-Lophuromys-Uranomys* (Denys *et al.* 1995), but the synapomorphic value of their similar pelage has not been evaluated at the microscopic level (many muroids possess texturally stiffened cover hairs) and few soft-organ systems have been investigated.

The use of Acomyinae for this subfamily, as loosely adopted in the recent literature (e.g. Dubois *et al.* 1999, Michaux & Catzeflis 2000), constitutes a *nomen nudum* and is unavailable from these works. The valid family-group name for the clade intended to contain the genera *Acomys*, *Deomys*, *Lophuromys* and *Uranomys* properly dates to Thomas's (1888) Deomyes, which he clearly designated as a suprageneric rank coordinate to his Mures (modern Muridae) and Criceti (approximately equal to modern Cricetidae).

Of the four genera, only *Acomys* has a well-documented fossil history, known from early Pliocene and Pleistocene sites in eastern and southern Africa (Denys 1990a, Senut *et al.* 1992, Avery 1998). The subfamily itself certainly originated earlier, as indicated by the extinct genus *Preacomys*, described from the late Miocene in Ethiopia and considered a progenitor of *Acomys* (Geraads 2001). Molecular clock estimates place the divergence between Deomyinae, Gerbillinae and Murinae as early Miocene, around 18–21 mya (Michaux *et al.* 2001).

Two of the four deomyine genera (*Deomys* and *Uranomys*) are monotypic and the others are moderately speciose. The number of species of *Acomys* and *Lophuromys* is uncertain. Here, 13 species of *Acomys* and 15 species of *Lophuromys* are recognized, although Musser & Carleton (2005) recognized 15 species of African *Acomys* and 21 species of *Lophuromys*.

Michael D. Carleton & Guy G. Musser

GENUS *Acomys* Spiny Mice

Acomys I. Geoffroy, 1838. Ann. Sci. Nat. Zool. (Paris), ser. 2, 10: 126. Type species: *Mus cahirinus* É. Geoffroy, 1803.

The genus contains 13–15 species (see above) widely distributed in Africa, and four additional species extraliminally in the Middle East (Musser & Carleton 2005; see also below). In Africa, all species occur in arid and semi-arid habitats, or in dry savannas, where rainfall is sparse and seasonal and daytime temperatures may be high.

The distinguishing characters of the genus are small size (HB rarely more than 120 mm), dorsal pelage largely composed of spines (the only genus of small rodent to have spines; hence their common name of 'spiny mice'), tail with large scales and clothed with bristle-like hairs, hindfeet broad and rather short, digits not reduced, and

accessory tubercles in addition to the normal pads on the palms and soles. Skull has broad flattened braincase; very large interparietal bone; long anterior palatal foramina extending posteriorly to mid-M¹; and the anterior half of mesopterygoid fossa is closed by plate-like outgrowths from the palatines, the open parts of fossa thus reduced to a small triangular space (Figure 40).

Spiny mice inhabit deserts and other dry areas, where they live mostly in sheltering rocky habitats. They are opportunistic feeders, eating seeds, leaves, dry plants, invertebrates such as snails, insects and their larvae. All species living in arid habitats have well-developed

physiological and behavioural characters for water conservation, although they are not as 'desert-adapted' as many other arid zone small rodents (e.g. *Gerbillus*, *Jaculus*). The reproductive biology of species in the genus is unusual among murid rodents: in those species studied so far, the young are precocious when born, a fact to which several social traits of behaviour are associated such as midwifery, social care of the young and the social rank of mothers (Dieterlen 1961, 1962, 1963). Spiny mice are rarely preyed upon by owls, probably because the spines of the pelage are unpalatable.

The genus *Acomys* is very complex, and the systematics and relationships within the genus are far from clear. The first attempt at a systematic revision using morphological characters was made by Ellerman (1941), who established a 'subspinosus-group' with only *A. subspinosus*, and a 'cahirinus-group' with three sections comprising 15 species, plus several subspecies; additional forms could not be

Acomys cahirinus.

Figure 40. Skull and mandible of *Acomys johannis* (HC 1118).

Table 19. Species in the genus *Acomys*. Arranged in order of increasing size.

| Species | GLS mean (mm) | HB mean (mm) | T (% of HB) | Colour of ventral pelage | Geographic distribution | Chromosome number (FN) | Dorsal pelage |
|-------------------------|---------------|--------------|-------------|--------------------------------|--|------------------------|--|
| <i>A. spinosissimus</i> | <26 | <90 | 87% | Pure white | Tanzania to South Africa | 60 (68) | Dorsal pelage grey, fawn or russet-brown; soft spines |
| <i>A. subspinosus</i> | <26 | <90 | 95% | Pure white | South Africa | 60 (70) | Dorsal pelage rusty-brown, bristle-like |
| <i>A. percivali</i> | >26 | 90–99 | 76% | Pure white | S Sudan, Uganda, Kenya, SW Ethiopia | n. d. | Dorsal pelage grey; strong spines mid-back to base of tail |
| <i>A. ignitis</i> | >26 | 90–99 | 77% | Pure white | Kenya, Tanzania | 50 (66–68) | Dorsal pelage brownish-orange, bright reddish-orange on flanks; broad slatted spines on rump |
| <i>A. cinererus</i> | >26 | 90–99 | 90% | Pure white | Sudan, Djibouti, Ethiopia | 48 (58) | Dorsal pelage greyish-cinnamon |
| <i>A. wilsoni</i> | >26 | 90–99 | 87% | Pure white | Somalia–Masai BZ | 50 (n. d.) | Dorsal pelage bright cinnamon or chestnut |
| <i>A. kempi</i> | >26 | 90–99 | 94% | Pure white | S. Ethiopia, S Somalia, Kenya, NE Tanzania | n. d. | Dorsal pelage orange-buff, strong coarse spines mid-back to base of tail |
| <i>A. louisae</i> | >26 | 90–99 | 109% | Pure white | Somalia and Djibouti | n. d. | Dorsal pelage rufous, buff or greyish-brown; tail comparatively long (ca. 122% of HB) |

allocated to any group due to lack of adequate material. Setzer (1975) produced a simple key which recognized five species (*A. cahirinus*, *A. dimidiatus*, *A. russatus*, *A. spinosissimus* and *A. subspinosus*) and 34 subspecies. A regional systematic revision of southern Africa was published by Dippenaar & Rautenbach (1986). Petter (1983) studied the pattern of molar teeth of the holotypes of *Acomys* spp. and, together with information from chromosome morphology (Matthey 1968), divided the genus into three groups, two of which belong to the subgenus *Acomys* and the third to a new subgenus *Peracomys* (*A. louisae*; Petter & Roche 1981) characterized by the presence of t7 on M¹ and M². Further insights into the complexities of the genus were highlighted by chromosomal reviews by Volobouev *et al.* (1991), Sokolov *et al.* (1993) and Kunze *et al.* (1999), and by biochemical and molecular analyses of species clusters by Janecek *et al.* (1991) and Barome *et al.* (2000). Denys *et al.* (1994) used chromosome and electrophoresis information, as well as morphological characters of the teeth and skull, and proposed a third subgenus, *Subacomys* (containing only *S. subspinosus*). Musser & Carleton (2005) commented that 'Regrettably, there is still no comprehensive taxonomic revision of the genus incorporating morphological as well as chromosomal and molecular data. Extant species are sorted into three subgenera (*Acomys*, *Peracomys* and *Subacomys*), but these grouping require reassessment by systematic revision' – a viewpoint that is maintained here.

Barome *et al.* (2001) presented two biogeographic hypotheses for the centre of origin of the genus and its dispersion. One suggests an origin in southern Africa and a northward dispersal along with subsequent evolution into species. The second suggests that East Africa is the centre – a hypothesis similar to that already made by Matthey (1968) – with dispersion and speciation in two directions, one northwards to the Mediterranean region and the other southwards to southern Africa. In both hypotheses, speciation could also have been caused by a progressive fragmentation resulting from the formation of the Rift Valley in its south-western part, and/or by the extension of tropical forest zones dividing the savanna regions into mosaics during climatic fluctuations, thus isolating the different species by vicariance.

Thirteen species (in Africa) are recognized here; in addition, Musser & Carleton (2005) recognized a further two species in Africa, *A. chudeaui* and *A. seurati*, which are here placed as synonyms of *A. cahirinus*. *Acomys dimidiatus* (perhaps also a subspecies of *A. cahirinus*) occurs in Sinai and further east and is not considered as an African species. The species are distinguished by size, pelage colour and texture, size, presence/absence of white spots on the head, number of palatal ridges, molar teeth characters and chromosome number (Table 19).

Fritz Dieterlen

Acomys airensis AÏR SPINY MOUSE (WESTERN SAHARAN SPINY MOUSE)

Fr. Souris épineuse de l'Aïr; Ger. Aïr-Stachelmaus

Acomys airensis Thomas and Hinton, 1921. Novit. Zool. 28: 8. Mount Baguezan, Asben (Aïr), Niger. 5200 ft (1580 m).

Taxonomy Musser & Carleton (1993) included *airensis* in *A. cahirinus*, but Volobouev *et al.* (1991, 1996a, b) clearly showed that chromosomal differences between these two forms (and between

them and *A. dimidiatus*) warrant a specific status for each. Molecular data show *A. airensis* to be the sister-group of a *A. cahirinus*/*A. minous*/*A. nesiotis*/*A. cilicicus* group within the '*cahirinus*–*dimidiatus*' complex (Barome *et al.* 2000). Conversely, the hypothesis that *A. chudeaui* from Morocco (karyotype described but not illustrated in Benazzou (1983) is conspecific with *A. airensis* can not be entirely ruled out. *Acomys chudeaui* would then be the correct name, predating *airensis*. Synonyms: none. Chromosome number: 2n = 40, 44 and 46 in Mali (Tranier *et al.* 1999, Dobigny *et al.* 2001b, L. Granjon and B. Sicard unpubl.), 2n = 40 in Mauritania (Bâ *et al.* 2001), 2n = 41 to 43 and 46 in Niger (Viegas-Péquignot *et al.* 1983, V. Volobouev & G. Dobigny unpubl.); all karyotypes have aFN = 66.

Description Small rodent with spiny dorsal hairs. Dorsal pelage orangey-grey, becoming paler on flanks; hairs whitish-grey at base, orangey subterminal band and grey at tip. Spiny hairs on the posterior half of the back, extending more towards the front in old individuals. Ventral pelage pure white, clearly delineated from colour of flanks. Head with pointed muzzle, small eyes and relatively large ears. Small white patch under eye more or less visible; white postauricular patch. Short hindfeet with short digits, Digit 1 being especially reduced in size. Tail moderately long (ca. 85–95% of HB). Skull remarkably flattened. Nipples: 1 + 2 = 6.

Acomys airensis

Geographic Variation Specimens from Air are smaller than those from Mali and Mauritania, with a relatively longer tail (see Measurements).

Similar Species

Acomys johannis. Pelage slightly to markedly darker; chromosome number: $2n = 66-68$; more southern distribution (right bank of Niger R.).

Distribution Endemic to Africa. Sahel Savanna BZ. Recorded from Mauritania, Mali on the left bank of Niger R. (with one exception; Tranier *et al.* 1999), and Niger. Would be also present in S Morocco if *chudeaui* is included in this species (but here included in *A. cahirinus*). The status of the specimens from S Algeria, with $2n = 38$ (referred to as *A. cahirinus* in Kowalski & Rzebik-Kowalska 1991), has to be ascertained.

Habitat Mostly found in rocky habitats, but also regularly in gardens and other human-related habitats, including huts (Bâ *et al.* 2001, Dobigny *et al.* 2001b, L. Granjon and B. Sicard unpubl.). One individual found in a completely sandy habitat of the inner delta of Niger R. (Tranier *et al.* 1999).

Abundance Probably locally abundant in favourable habitats, as suggested by relatively high trapping success in rocky habitats where found in Mauritania and Mali (K. Bâ and L. Granjon unpubl.).

Remarks Terrestrial and probably mainly nocturnal, although two specimens from Air were captured by day (labels, MNHN). May rest in rock cracks rather than in ground burrows. As in other *Acomys* species, the skin is very delicate and tears off the tail easily. In captivity, omnivorous and readily carnivorous. In S Mauritania,

pregnant ♀♀ were found in Aug (4 of 8) and Oct (2 of 5). Mean embryo number: 2.2 (range 2–3, $n = 9$; K. Bâ & L. Granjon unpubl.). Heavily preyed upon by Barn Owls *Tyto alba* on an inselberg in C Mali (near Niafunké; L. Granjon unpubl.).

Conservation IUCN Category: Least Concern.

Acomys cahirinus CAIRO SPINY MOUSE (NORTHEAST AFRICAN SPINY MOUSE)

Fr. Souris épineuse du Caire; Ger. Kairo Stachelmaus

Acomys cahirinus (Geoffroy, 1803). Catalogue des Mammifères du Museum National d'Histoire Naturelle, p. 195. Cairo, Egypt.

Taxonomy Originally described in the genus *Mus*. The definition of *A. cahirinus* has been a subject of controversy, and several forms originally considered within 'cahirinus' are now recognized as separate species. *Acomys cahirinus*, as currently understood, is centred on NE Africa (with some forms in the Middle East) and can be distinguished from related forms by patterns of molar teeth (Denys *et al.* 1994), chromosome number (Volobouev *et al.* 1991, 1996a), and mitochondrial DNA cytochrome *b* sequences (Barome *et al.* 2000). Musser & Carleton (1993) listed 16 forms of *A. cahirinus* as synonyms, of which five are non-African. Currently, four of these African forms are regarded as separate species (*A. airensis*, *A. chudeaui*, *A. dimidiatus*, *A. seurati*) by Musser & Carleton (2005) and Denys *et al.* (1994). Here, *A. airensis* is given specific rank; in contrast, the other three forms are not given specific rank because, at the time of study, it was assumed that the correct name was 'A. cahirinus' and hence biological information collected for *A. cahirinus* may, in fact, be referable to one of these other forms. The 'cahirinus group' as a whole is in need of revision (Osborn & Helmy 1980, F.

Dieterlen unpubl.). Synonyms: *albigena*, *chudeaui*, *dimidiatus*, *helmyi*, *hunteri*, *megalodus*, *nubicus*, *sabryi*, *seurati*, *viator*. Subspecies: possibly five. Chromosome number: $2n = 36$, FN = 68 in Sinai/Egypt (Wahrman & Goitein 1972), Egypt (Togby *et al.* 1972, De Hondt *et al.* 1977) and Ethiopia (Sokolov *et al.* 1993). A different karyotype of *A. cahirinus* ($2n = 38$, FN = 68) (Wahrman & Zahavi 1953) in Israel and E Sinai hybridizes along a narrow strip of land of eastern Sinai with $2n = 36$, so producing $2n = 37$, FN = 68 (Wahrman & Goitein 1972).

Description Small mouse although large for the genus. Fine hairs on back of head and neck, stiff hairs on anterior part of back, spines (with longitudinal groove on upper surface) from shoulder to rump. Dorsal pelage pale to dark brown, or pale to dark cinnamon; colour varies geographically; hairs and spines white or pale grey at base, with cinnamon subterminal band, and black tip (mid-dorsal spines only). Ventral pelage pure white. Head similar in colour to dorsal pelage. Ears pigmented, covered with short whitish hairs.

White basal and postauricular patches. Eyes large, dark; conspicuous white suborbital spot. Limbs short. Feet white. Tail relatively long (90–100% of HB, depending on population), with scales, almost naked with scattered short bristles, brownish above, whitish below; tail often short or absent due to injury. Nipples: $1 + 2 = 6$.

Geographic Variation Following Osborn & Helmy (1980) five subspecies from Egypt and partly from Sudan are recognized provisionally: *A. c. cahirinus*, *A. c. helmyi*, *A. c. hunteri/nubicus*, *A. c. megalodus* and *A. c. viator*. Subspecifically, colour of dorsal pelage varies from dark brown (*hunteri*, *viator*) to pale brown (*helmyi*) to slate-grey (some *cahirinus*). *Acomys c. helmyi* is the largest subspecies (mean HB: 118 mm), and *A. c. cahirinus* from Bahariya Oasis is the smallest (mean HB: 98 mm) (Osborn & Helmy 1980). There are intergradations in colour, and overlap in measurements, between subspecies. Commensal individuals in the Nile Valley and Delta are often melanistic.

Similar Species

A. cineraceus. On average slightly smaller, tail shorter; geographic range further south in Sudan and Ethiopia.

Distribution Endemic to Africa. Sahara Arid and Sahel Savanna BZs and northern part of Somalia–Masai Bushland BZ. Recorded from most parts of Egypt including Sinai, Sudan (north of ca. 16°N), Eritrea, Djibouti and Ethiopia (five localities in the Rift Valley; Sokolov *et al.* 1993). Limits in C and S Sudan, and in Ethiopia uncertain. Less widely distributed in Libya (*viator*; Ranck 1968), Algeria (*seurati*; Kowalski & Rzebik-Kowalska 1991) and Morocco (*chudeaui*; Aulagnier & Thévenot 1986).

Habitat Rocky hillsides, cliffs, boulder-strewn canyons and other rocky habitats. May also occur in sandy desert habitats where there are date palms. Some populations live in human-made structures – houses, huts, tombs and temples – where holes and crevices provide

shelter. The five desert subspecies of Egypt and (partly) Sudan (Osborn & Helmy 1980) may also be found in settlements and local huts (Hoogstraal *et al.* 1957a). Altitude appears to have no effect on distribution as long as food is available (Hoogstraal *et al.* 1957b).

Abundance Common in suitable habitats. Numbers vary considerably between localities, and show some evidence of fluctuating annually (Osborn & Helmy 1980).

Adaptations In Egypt, activity is predominantly in the early morning and in the late afternoon (Osborn & Helmy 1980), although in N Sudan most activity occurs at night (Happold 1967c). On jebels (isolated rocky hills), live under boulders and in crevices of rocks where protected from heat and predators. Extremely agile, running quickly over and around rocks and boulders.

Foraging and Food Herbivorous and partly omnivorous. The diet is mainly seeds of herbs and grasses. Where plants are rare or lacking, Cairo Spiny Mice can forage on windblown plant remains trapped in crevices. In some areas, dates may be a staple food. Insects such as locusts, crickets, butterflies and moths are readily eaten and, on some occasions, desert snails (e.g. *Eremica desertorum*) are a preferred food. By eating desert snails, these spiny mice can compensate for high evaporative water loss (Shkolnik & Borut 1966, 1969). Unlike jerboas and jirds, they are unable to subsist for more than nine days without water-containing food. Licking dew from stones and plants could also provide some water.

A further kind of natural food may be undigested organic matter in the faeces of fruit bats (*Rousettus aegyptiacus*), which roost during the day in tombs of the Nile Valley (Maser 1966, Osborn & Helmy 1980). A strange source of food can be (or was) dried flesh and bone marrow of mummified humans in the tombs in Egypt (Osborn & Helmy 1980).

Social and Reproductive Behaviour Appears to live in social groups, mostly mothers and their offspring. Within a group there is a rank order, and individuals exhibit typical social behaviour such as mutual grooming. Females assist in birth and care of young (Dieterlen 1961, 1962, 1963). Similar behaviour is shown by *A. dimidiatus* and *A. minous* (a non-African species). See also profile Genus *Acomys*.

Reproduction and Population Structure Gestation: 38 days (range 36–40) in captive animals (Dieterlen 1961; as *A. c. dimidiatus*); 42 days (Bodenheimer 1949, see also Harrison & Bates 1991). Mean litter-size: 2.4 (range 1–5, $n = 123$; Dieterlen 1961). Young altricial at birth; maturity: 2–3 months.

Predators, Parasites and Diseases Generally, relatively rare in pellets of birds of prey. In middle Egypt, no remains of *Acomys* found in pellets of the Long-eared Owl (*Asio otus*) ($n = 590$; 91% of prey was *Mus musculus*; Handwerk 1990). In N Sudan (jebels north of Omdurman), pellets of the Desert Eagle-owl *Bubo ascalaphus* contained only six individuals of Cairo Spiny Mice (= 3.3% of prey items; $n = 182$); other prey items included *Gerbillus gerbillus* (ca. 26%), *Meriones crassus* (ca. 24%), *Gerbillus pyramidum* (ca. 19%), *Jaculus jaculus* (ca. 18%), *Desmodilliscus braueri* (ca. 8%) and *Arvicanthis niloticus* (ca. 1.2%) (F. Dieterlen unpubl.). In Egypt, *Parapulex*

Acomys cahirinus

chephrensis is the commonest species of flea found on *A. cahirinus*; other species include *Xenopsylla cheopis*, *Synosternus cleopatrae*, *Pulex irritans* and *Ctenocephalides felix* (Hoogstraal & Traub 1965b).

Acomys cahirinus is a possible reservoir for communicable arthropod-borne diseases (Hoogstraal *et al.* 1967). Of 92 serum samples from the Eastern Desert of Egypt, a relatively large percentage was positive for rickettsioses of humans: 34 contained *Rickettsia prowazekii*, responsible for epidemic louse-borne typhus; 5 were positive for *Rickettsia conorii*, responsible for tick-borne boutonneuse fever; and 11 for *Coxiella burnetii*, the mostly airborne causal organism of Q-fever.

Conservation IUCN Category: Least Concern.

A widespread, adaptable and common species.

Acomys cineraceus GREY SPINY MOUSE (HEUGLIN'S SPINY MOUSE)

Fr. Souris épineuse de Heuglin; Ger. Heuglins Stachelmaus

Acomys cineraceus Heuglin & Fitzinger, 1866. Sitz. K. Akad. Wiss. Wien 54: 573.

Doka, eastern Sennaar, between the Atbara and Rahad rivers of Sudan.

Taxonomy Although originally described from Sudan as a valid species, often included within *A. cahirinus* (e.g. Setzer 1956, 1975, Happold 1969). Bates (1994, map) provisionally included the spiny mice from West Africa (Niger, Nigeria, Benin, Togo, Burkina) in *A. cineraceus*. Recent studies have clarified the status of these forms: the spiny mice of West Africa are now considered to represent *A. airensis* (Volobouev *et al.* 1991, 1996a), *A. johannis* and *Acomys* sp. 1 and *Acomys* sp. 2 (as yet undescribed) (Barome *et al.* 2000). *Acomys cineraceus* is now restricted to the spiny mice in parts of Sudan and W Ethiopia, and is karyotypically distinguished from other species in the genus (Kunze *et al.* 1999). Now considered as one of four species of *Acomys* occurring in Sudan (the others being *A. wilsoni*, *A. percivali* and *A. cahirinus*). Synonyms: *cinerascens* (a mis-spelling by Heuglin in 1877), *hawashensis*, *hystrella*, *intermedius*, *lowei*, *witherbyi*. Subspecies: none (but see Geographic Variation). Chromosome number: 2n = 48 or 50 (Ingessana Hills, Sudan); 2n = 50, FN = 59 (nine metacentrics) and 2n = 48, FN = 58 (ten metacentrics) (Kordofan, Sudan); 2n = 48 (Kunze *et al.* 1999).

Description Small spiny mouse with greyish-cinnamon pelage. Fine hairs on back of head and neck, and somewhat longer on anterior part of back. Dorsal pelage greyish or blackish-grey (see Geographic Variation); anterior part of back, flanks and sides of rump cinnamon. Ventral pelage pure white. Head with small whitish spots below each eye and behind each ear. Limbs and feet white or cream. Tail moderately long (ca. 90% of HB), upper surface darkish with short darkish bristles, below pale with whitish bristles. Nipples: 1 + 2 = 6.

Geographic Variation Three geographic forms recognizable in Sudan: (1) Dorsal pelage blackish-grey, flanks reddish-cinnamon, ventral pelage white (most parts of Blue Nile Province to east of southern Kordofan). (2) Dorsal pelage grey or greyish-black, flanks similar to dorsal pelage and without any reddish/cinnamon, ventral pelage white (E Sudan near to the Ethiopian border where annual

Acomys cineraceus

rainfall 700–1000 mm). (3) Similar to the above but colours are muted and only weakly contrasting (northern part of range, 13–15° N from Kassala to Darfur where annual rainfall 150–400 mm).

Similar Species

A. cahirinus. On average larger and tail longer; dorsal pelage pale to dark brown, or pale to dark cinnamon; distribution mostly further north, but may be parapatric in N Sudan.

A. percivali. On average smaller; dorsal pelage grey to greyish-brown, without any cinnamon or russet; distribution mostly further south in East Africa but may be parapatric in S Sudan.

A. wilsoni. Similar size; dorsal pelage bright cinnamon or chestnut; distribution further south in East Africa but may be parapatric in S Sudan.

Distribution Endemic to Africa. Recorded from Sudan, Ethiopia and Djibouti. In Sudan, known from south of ca. 17°N; widespread but localized in S, E and W Sudan, but less widespread in SW Sudan. Not recorded further west than W Sudan, e.g. not recorded in NE DR Congo (Garamba N. P., Verheyen & Verschuren 1966), nor in E Central African Republic (Petter & Genest 1970). Happold (1969) pointed out that the distribution of species of *Acomys*, as inhabitants of rocky regions and now mostly confined to jebels, expanded and contracted depending on climatic conditions during the past 15,000 years. They may have occurred in localities in parts of the present woodland savanna as well as on jebels, and many populations may have been continuously distributed.

Habitat *Acomys cineraceus* (and *A. cahirinus*) is the most typical rodent of the Sudanese rocky regions, especially on isolated rocky hills (jebels), mostly formed of granite and syenite, where boulders and crevices provide for shelter and for retaining grasses, seeds and moisture (Happold 1969). Not recorded in open arid sandy regions of N Sudan. These rocky islands project from the wide extensive plains, and are numerous in the provinces of Kassala, Blue Nile and Upper Nile in E Sudan, and also in the wooded savannas of S Sudan, mostly at low altitudes between 200 and 500 m. Also recorded from villages, huts in villages and other buildings in Upper Nile and Blue Nile Provinces. Further south, in C and S Sudan, found in fields, dry wooded savanna and at edges of swamps and grasslands (specimen labels) (F. Dieterlen unpubl.).

Abundance Probably similar in abundance to *A. cahirinus*. Often abundant in suitable habitats and the most numerous of small rodents. In N Sudan, comprised 80–94% of small mammals on four rocky jebels (n = 22–58/jebel; usually only 2–3 spp. on each jebel), and 0% on two other jebels (no small rodents present) (Happold 1969).

Adaptations Terrestrial and rupicolous; nocturnal and crepuscular. Colour of pelage is dependent on climate and environment (see Geographic Variation). Habitat restriction to jebels and other rocky habitats appears less pronounced in the acacia savannas of SE and S Sudan (e.g. Upper Nile and Equatoria Province) than in N Sudan. In S Sudan, occurs sympatrically with one of more of the following: *Acomys*

wilsoni, *A. percivali*, *Myomys fumatus*, *Aethomys hindei*, *Lemniscomys macculus*, *L. zebra* and *Mastomys* sp.

Foraging and Food Probably opportunistic and omnivorous. No detailed analysis of diet available, but probably varies seasonally and includes seeds of petrophilous plants, snails of several species, insects and their larvae, spiders and scorpions.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure In N Sudan (Blue Nile and Khartoum Provinces), pregnant ♀♀ and many young animals in Nov and Dec; probably one breeding season/year 1–3 months after the rains (Happold 1966a). Further south (also Blue Nile Province), pregnant or lactating ♀♀ in Nov (n = 4) and in the wet season May and Jul (n = 7); probably two breeding seasons/year (F. Dieterlen unpubl.). In W Equatoria Province, S Sudan, almost 100% of adult ♀♀ were pregnant or lactating (n = 18) at the end of the wet season (Sep–Oct). Gestation: uncertain, probably 30–35 days. Mean embryo number: 2.53 (range 1–5; n = 30 pregnancies). Young precocial at birth with eyes open. Sexual maturity (♀♀ and ♂♂): ca. 2 months when body weight ca. 30 g. Adult ♂♂ have testes size of 10–13 mm at all times; no evident change in size during breeding season (F. Dieterlen unpubl.).

Predators, Parasites and Diseases See *A. cahirinus*.

Conservation IUCN Category: Least Concern.

Acomys ignitus FIERY SPINY MOUSE

Fr. Souris épineuse rougeâtre; Ger. Rote Stachelmaus

Acomys ignitus Dollman, 1910. Ann. Mag. Nat. Hist., ser. 8, 6: 229. Voi, Kenya.

Taxonomy Recognized as a valid species by Hollister (1919) and Ellerman (1941), and confirmed as such by recent studies on chromosomes (Matthey 1965), electrophoretic analyses (Janacek *et al.* 1991) and cytochrome *c* (Barome *et al.* 2000). Janacek *et al.* (1991) regard *A. ignitus* as closely related to *A. cahirinus*. The taxon

kempi, considered as a subspecies by Dollman (1914), Hollister (1919) and Ellerman (1941), has proved to be a valid species and its geographic range is well separated from that of *A. ignitus*. Synonyms: none. Chromosome number: 2n = 50; FN 66–68; with 16–18 meta- and submetacentric chromosomes (Matthey 1965).

Description A small 'handsome' species with bright reddish-orange flanks. Thin spinous hairs on head, shoulders, anterior part of back, and flanks; broad and flattened spines on rump and posterior part of back. Dorsal pelage brownish-orange, becoming bright reddish-orange ('fiery') on flanks; hairs slate-grey at base. Ventral pelage white, hairs rather spinous, pure white; sharply delineated from the reddish-orange flanks. Upper surface of hands and feet white. Tail relatively short (ca. 77% of HB), stout and comparatively coarse, silvery-grey, with black bristles above, white bristles below. For details of special characters of teeth, see Denys *et al.* (1994).

Geographic Variation None recorded.

Similar Species

A. kempi. Similar head and body size; dorsal pelage orange-buff with stiff spines on mid-back, flanks dull orange; tail longer (mean 93 mm) and relatively longer (ca. 95% of HB); sympatric but with more widespread distribution.

A. wilsoni. Similar head and body size; dorsal pelage bright cinnamon or chestnut; tail slightly longer (mean 84 mm) and slightly longer (ca. 90% of HB); often common and more widespread.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from SE Kenya (22 known localities) and NE Tanzania (one locality – Usambara Mts) (Janecek *et al.* 1991, Bates 1994). In Kenya, found mostly in the region of Tsavo N. P. at altitudes between ca. 100 m and 800 m. In addition, there is a record from Somalia (Petter 1983), but without a locality (and hence not shown on map).

Habitat In Kenya, occurs mostly in rocky habitats in dry savanna and semi-desert in the region of Tsavo N. P. at altitudes between ca. 100 m and 800 m. Most of the known habitats are in the region of Tsavo N. P.

Abundance No information.

Remarks Apparently little information. Litter-size: 1.5 (1–2, n = 4; Hollister 1919).

Conservation IUCN Category: Least Concern. However, the small geographic range suggests it may be 'Near Threatened'.

Acomys johannis JOHAN'S SPINY MOUSE

Fr. Souris épineuse de Johan; Ger. Johans Stachelmaus

Acomys johannis Thomas, 1912. Ann. Mag. Nat. Hist., ser. 8, 9: 272. Kabwir, Bauchi Plateau, Nigeria.

Taxonomy Previously included in *A. cineraceus* (Musser & Carleton 1993), but now considered to be a distinct species (Musser & Carleton 2005). Rosevear (1953) referred to this species as *A. johannis*; later (1969), he referred to *Acomys cahirinus johannis*, but also included specimens now considered to be *A. airensis*. Referred to as *A. cahirinus johannis* by Happold (1987). Barome *et al.* (2000) demonstrated the molecular proximity of specimens from Nigeria, Cameroon, Benin and Niger. '*Acomys* sp. 1' of Barome *et al.* (2000) from Burkina also considered here to be *A. johannis*. Synonyms: none.

Chromosome number: 2n = 66–68 (Volobouev *et al.* 1996b).

Description Small spiny mouse with brownish-grey pelage. Dorsal pelage chocolate-brown to grey, becoming paler on flanks; hairs brown to grey at base, with darker tip; spiny hairs on posterior half of the back, extending more anteriorly in old individuals. Ventral pelage entirely white; clearly delineated from flanks. Head with pointed muzzle, small eyes and relatively large ears. Hindfeet short with short digits, Digit 1 being especially reduced in size. Tail

moderately long (ca. 90% of HB), easily breakable, bicoloured (grey-brown above, white below) and naked (with the exception of very short hairs at tip). Nipples: $1 + 2 = 6$.

Geographic Variation Size and colour variation in Burkina, where brown individuals from S are significantly larger than grey and rufous individuals from C and N (Sicard & Tranier 1996).

Similar Species

A. airensis. Pelage slightly paler; chromosome number: $2n = 40-46$; more northern distribution (Mauritania, Mali and Niger [left bank of the Niger R]).

Distribution Endemic to Africa. Sudan Savanna and Sahel Savanna BZs. Recorded from Mali and Niger (right bank of Niger R.), Burkina, N Togo, Benin, Ghana, Nigeria, N Cameroon and Chad.

Habitat Found mainly in rocky habitats such as rock ledges, cliffs, small inselbergs and extensive rocky hills in Burkina (Sicard & Tranier 1996), Chad (Granjon *et al.* 2004), Mali (L. Granjon unpubl.) and Nigeria (Happold 1970b), but sometimes caught at some distance from rocks, in dense vegetation or near small water-courses, as in S Burkina (Sicard & Tranier 1996).

Abundance Locally abundant in favourable habitats, as suggested by relatively high trapping success in rocky habitats where it was found in Burkina (B. Sicard pers. comm.) and Chad (Granjon *et al.* 2004). Comprised 95% of small rodents on sandstone rocks in Yankari G. R., Nigeria ($n = 19$; Happold 1970b).

Remarks Terrestrial and nocturnal. Rests in rock cracks rather than ground burrows, and occasionally uses cracks in termitaria (Sicard & Tranier 1996). As for other *Acomys*, the skin is very delicate and the tail breaks easily. In captivity, omnivorous and readily carnivorous. Pregnant ♀♀ at end of dry season (Mar–Apr) in Yankari G. R., Nigeria; no data for other months. Mean embryo number: 1.4 (range 1–2, $n = 5$; Happold 1970b). One female with two embryos in Mali (L. Granjon unpubl.).

Conservation IUCN Category: Least Concern.

Acomys kemp KEMP'S SPINY MOUSE

Fr. Souris épineuse de Kemp; Ger. Kems Stachelmaus

Acomys kemp Dollman, 1911. Ann. Mag. Nat. Hist., ser. 8, 8: 125. Chanler Falls, N Guaso Nyiro, Kenya.

Taxonomy Originally described as a species by Dollman (1911a), but later considered to be a subspecies of *A. ignitus* by the same author (Dollman 1914) (see also Hollister 1919 and Ellerman 1941). Treated as a subspecies of *A. cahirinus* by Setzer (1975), but reinstated as a species by Janeczek *et al.* (1991). Musser & Carleton (1993, 2005) also refer to *kemp* as a distinct species on the basis of morphological characters and distribution, and consider it to be an eastern segment of *A. cineraceus*. Synonyms: *montanus*, *pulchellus*. Subspecies: none. Chromosome number: not known.

Description Small spiny mouse with orange-grey pelage. Pelage stiff and coarse, spines (up to 10 mm) from mid-back to base of tail and on rump. Dorsal pelage orange-buff, darker on mid-dorsal line; not speckled; pale grey at base, orange-buff at tip. Flanks dull orange; hairs soft, whitish-grey at base, orange at tip. Ventral pelage pure white, colour sharply delineated from flanks. Head similar in colour to back. Cheeks orange-buff (as flanks); lips, chin, throat and chest white. White suborbital spot. White subauricular patch. Fore- and hindlimbs short. Feet white. Tail relatively long (ca. 94% of HB),

scaly, almost naked, brownish-grey above with black bristles, paler below with whitish bristles. Nipples: not known.

Geographic Variation None recorded.

Similar Species

A. ignitus. Similar size; dorsal pelage brownish-orange, with bright reddish-orange flanks; tail shorter (70–85 mm) and relatively shorter (ca 77%) than HB; low altitudes, SE Kenya and N Tanzania.

A. wilsoni. Similar head and body size; dorsal pelage bright cinnamon or chestnut; tail shorter (mean 84 mm) and relatively slightly shorter (ca. 85% of HB); often common.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from S Ethiopia, S Somalia, Kenya and NE Tanzania. In Kenya, known only from 20 localities east of the Rift Valley between the Equator and ca. 03° 00' N, and from 37° 15' E to ca. 39° 00' E. In Ethiopia, known from three localities in S Sidamo Province, all east of the Rift Valley; northern limit ca. 06° 40' N. One record from NE Tanzania (Musser & Carleton 1993) and one record from S Somalia. Limits unknown; Gregorian Rift Valley appears to be western limit of distribution. Altitudinal range ca. 600–1800 m.

Habitat Rocky habitats in dry savanna and semi-desert.

Remarks Embryo numbers: 1 (n = 1), 2 (n = 1) (Hollister 1919). Apparently no other information available.

Conservation IUCN Category: Least Concern.

Acomys louisae LOUISE'S SPINY MOUSE

Fr. Souris épineuse de Louise; Ger. Louises Stechelmaus

Acomys louisae Thomas, 1896. Ann. Mag. Nat. Hist., ser. 6, 18: 269. Henweina Plain, 40 miles south of Berbera, Somalia.

Taxonomy The only representative of the subgenus *Peracomys*, characterized by the possession of a t7-cusp on M1 and/or M2 that is not present in the subgenus *Acomys* (Petter & Roche 1981). This character is found in *Acomys* from a large area in Somalia, Ethiopia, Kenya and N Tanzania and is probably evidence of an unrecognized species-complex (Petter 1983). Synonyms: *umbratus*. Subspecies: two. Chromosome number: not known.

Description Small and relatively long-tailed spiny mouse. Pelage spiny from shoulders to base of tail. Dorsal pelage rufous, buff or greyish-brown; hairs and spines dull brown, slightly darker at tip. Flanks similar to dorsum, stiff (not spiny), without any russet colour. Ventral pelage pure white, soft; colour clearly delineated from colour of flanks. Ears darkly pigmented, with scattered short whitish hairs on inner surface. Subauricular patch small (or absent). Pelage colour

varies geographically. Limbs and feet white. Tail relatively long (ca. 109% of HB), the relatively longest tail of any species in the genus, usually bicoloured, greyish-brown above, white below.

Geographic Variation

A. l. louisae: Henweina Plain, 40 miles S of Berbera. Dorsal pelage rich buff or ochre-buff; tail mostly all white.

A. l. umbratus: Wagar Mountain, Golis Mts, N Somalia. Dorsal pelage greyish-brown, paler on rump; tail bicoloured.

Similar Species

A. kemp. On average HB larger; T similar in length but relatively shorter than HB; dorsal pelage orange-buff.

A. mullah. HB larger; T on average slightly longer but relatively shorter than HB; dorsal pelage slate-grey.

A. wilsoni. HB similar in length; T shorter, and relatively shorter than HB; dorsal pelage pale brown, speckled.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from N, NE and E Somalia, north of ca. 06°N (ten localities), and Djibouti. Probably extends to S Somalia; limits uncertain (D. Schlitter, pers. comm.).

Habitat Little information; recorded from coastal plains to ca. 1500 m (Petter & Roche 1981).

Abundance Presumably uncommon or rare; few records.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Measurements

Acomys louisae

Acomys mullah MULLAH SPINY MOUSE

Fr. Souris épineuse de Mullah; Ger. Mullah-Stachelmaus

Acomys mullah Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 103. Harar, Ethiopia.

Taxonomy Setzer (1975) treated *mullah* together with *brockmani* (Dollman 1911b) as subspecies of *A. dimidiatus*. Ellerman (1941) recognized *mullah* and *brockmani* as distinct species. Yalden *et al.* (1976) and Musser & Carleton (1993) included *mullah* as a synonym of *A. cahirinus*. Here, following Musser & Carleton (2005), *mullah* is retained as a valid species pending revision. Synonyms: *brockmani*. Subspecies: none. Chromosome number: not known.

Description Small greyish spiny mouse. Hairs spiny and long from shoulders to base of tail. Dorsal pelage slate-grey, becoming brownish on rump; spines off-white at base, pale brown or dark brown at tip. Flanks brownish. Ventral pelage soft, white; clearly delineated from colour of flanks. Head similar in colour to dorsal pelage. Ears large, pigmented with sparse covering of short blackish-brown hairs. Small white subauricular patch. Outer surface of forelimbs brownish. Fore- and hindfeet white. Tail relatively long (ca. 100% of HB), bicoloured, grey above, white below, with sparse covering of hairs. Skull very large, braincase broad and flat, ridges not very heavy; anterior palatal foramina very long reaching nearly to posterior end of M¹. Nipples: 0 + 2 = 4.

Acomys mullah

Geographic Variation The form *brockmani* differs from *mullah* (as above) in being slightly smaller; dorsal pelage pale yellow with rufous tint becoming darker on rump and less spiny; flanks slightly reddish, paler than in *mullah*; skull smaller with shorter anterior palatal foramina.

Similar Species

- A. louisae*. Smaller, dorsal pelage rufous, buff or greyish-brown; distribution possibly partly sympatric.
A. cahirinus. Dorsal pelage russet; on average smaller; more widespread in NE Africa.
A. percivali. Dorsal pelage dark brownish-grey; on average smaller; allopatric.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from Ethiopia (type locality Harar) and Somalia (Upper Sheikh, Berbera, Bulhar); probably occurs in Eritrea and Djibouti. Limits unknown.

Habitat Specimens captured among rocks, on stony ground amongst crops; and in ‘bush country’ (R. S. Drake-Brockman, specimen labels; BMNH).

Abundance Very rare; only known from a few specimens from about four localities.

Remarks Nocturnal. Subadults (HB: 90–100 mm) recorded in Aug, Sep, Nov, Dec, Jan and Mar (BMNH).

Conservation IUCN Category: Least Concern.

Measurements

Acomys mullah

Acomys percivali PERCIVAL'S SPINY MOUSE

Fr. Souris épineuse de Percival; Ger. Percivals Stachelmaus

Acomys percivali Dollman, 1911. Ann. Mag. Nat. Hist., ser. 8, 8: 126. Chanler Falls, Nyiro, Kenya.

Taxonomy Included as a synonym of *kemp*i and included within *A. cahirinus* by Setzer (1975), although most authors (e.g. Neal 1983, Petter 1983) consider *A. percivali* to be a valid species. Genetically closely related to *A. wilsoni* (Janacek *et al.* 1991). Synonyms: none. Chromosome number: not known.

Description Small grey spiny mouse. Pelage coarse and stiff with strong spines (ca. 10 mm) from mid-back to base of tail. Dorsal pelage grey to greyish-brown (mostly without any russet or reddish colouration as in other species of the genus); hairs/spines pale grey at base, darker grey at tip. Flanks grey, usually paler than dorsal pelage (occasionally with some cinnamon on flanks). Ventral pelage white, usually not stiff or spiny. Colour of ventral pelage clearly delineated from colour of flanks. Adult ♂♂ may have a patch of yellow, oily pelage from secretions of scent glands on centre of abdomen. Head similar in colour to dorsal pelage. Some individuals have small white suborbital spot. Ears large, darkly pigmented, sparsely covered with short small hairs. Subauricular and postauricular spots absent. Chin, throat and chest white. Hindlimbs and feet short; feet white above with strong claws. Tail short (ca. 76% of HB), almost naked but with scattered short bristles; grey above, whitish-grey below. Tail often absent or short due to injury. Nipples: not known.

Geographic Variation None recorded.

Acomys percivali

Similar Species

A. wilsoni. Similar head and body size; dorsal pelage bright cinnamon or chestnut; tail on average longer (mean 84 mm) and relatively longer (ca. 87% of HB); frequently syntopic; often common.

A. kempii. Similar head and body size; dorsal pelage orange-buff with stiff spines on mid-back, flanks dull orange; tail longer (mean 93 mm) and relatively longer (ca. 95% of HB); distribution restricted.

A. ignitus. Similar head and body size; dorsal pelage brownish-orange, with bright reddish-orange flanks; tail relatively and comparatively similar; restricted to low altitudes in SE Kenya and N Tanzania.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ (part). Recorded from S Sudan (east of the White Nile), Uganda, Kenya and SW Ethiopia. Limits of distribution uncertain.

Habitat Kopjes and rocky habitats. The rodent fauna on kopjes in C Kenya is nearly always dominated by this species, sometimes to the near or total exclusion of all other species. On the exceedingly rare occasions when Percival's Spiny Mice are captured in other habitats, circumstances suggest they are almost certainly dispersing individuals.

Abundance Very common on kopjes, and often the most numerous species of small mammal, comprising 80–100% of total small rodents captured. Densities vary but are usually 100–300/ha (S. Takata unpubl.). Populations tend to be stable because these mice breed slowly and are long-lived. Even small kopjes may have stable populations. May be syntopic with *A. wilsoni* on some kopjes.

Adaptations Nocturnal and terrestrial. Percival's Spiny Mice are surprisingly good climbers on sloping, vertical and overhanging rocky walls. They are able to run and climb as readily as the agamid lizards that also live on the kopjes. At night, they run across open expanses of rock while foraging. They are also accomplished jumpers, and captives often leap half a metre into the air, somersaulting, and landing upside-down on the wire top of the enclosure. Their forelimbs are particularly dexterous, perhaps as a modification to help capturing insects. When threatened, Percival's Spiny Mice wedge themselves head-first into narrow cracks so that only the tail and spines protrude. Once the tail is pulled off, there is nothing left for predators to secure. The body is remarkably supple and, when wedged into a crevice, can be dorsoventrally flattened to the height of the skull.

Foraging and Food Omnivorous, but strongly insectivorous. Diet varies seasonally. In the dry season, diet comprises 60–95% arthropods and 5–10% stems, leaves or seeds; in the wet season 70–90% arthropods, 5–20% stems and leaves and 5–10% seeds; and in the intermediate season (between wet and dry) 45–50% arthropods, 10–25% stems and leaves and 35–40% seeds (Neal 1984a). The diet may also include gum exudates (Neal 1984b). Wild-caught captives in cafeteria-style feeding trials feed almost exclusively on insects (over 95% by weight) (S. Takata unpubl.). Percival's Spiny Mice are very adept at capturing large orthopterans, biting their legs off to immobilize them before eating (S. Takata unpubl.). When offered large flying moths, they will leap into the air to capture them. If given a choice of seeds, they prefer those of *Rhynchelytrum repens*, a kopje grass with relatively large seeds (S. Takata unpubl.). Preference for this seed is suggested also by the empty husks of seed heads of *R. repens* found on well-used paths through and under rocks on kopjes.

Social and Reproductive Behaviour Highly social. Spool-and-line tracking of individuals shows that on small and medium-sized

kopjes, each mouse uses the entire kopje with no obvious territoriality shown by either sex. In captivity, they are very social, sleeping together and grooming each other. In captivity, adults of both sexes groom and carry young animals; however, when densities are high, larger dominant mice, particularly ♀♀, become aggressive and may attack and kill younger individuals when they reach 1–2 months of age.

Reproduction and Population Structure Reproduction on a single kopje is highly synchronous, with all adult ♀♀ often giving birth within days of one another. However, there is little synchrony between nearby kopjes, and kopjes separated by only 1–2 km are completely out of synchrony. In Meru N. P., Kenya, pregnant ♀♀ were present throughout the year; the occurrence of pregnancy varied from ca. 45% to ca. 90%/month and was not closely associated with seasonal changes in rainfall (cf. syntopic *Gerbilliscus nigricaudus*) (Neal 1984a). Gestation: 34–35 days (S. Takata unpubl.). Mean litter-size: 1.85 (Neal 1983), 1.88 (S. Takata unpubl.). Weight of full-term embryos: 4–5 g (Neal 1983). At birth, young weigh 4–5.5 g (S. Takata unpubl.), and are precocious, fully haired with soft pelage, able to follow their mother and to feed on solid food. Spines erupt as young approach five weeks of age, and weigh 8–20 g. At this time, growth rates slow noticeably. Percival's Spiny Mice are long-lived: individuals marked as adults have been recaptured three years later on the same kopje. Dispersal seems to be rare as few marked animals (over a six-year period) have been found on other kopjes after disappearing from their natal kopjes (Kenya; S. Takata unpubl.).

Predators, Parasites and Diseases Remains have never been recovered from the faecal samples from over 300 small mammalian carnivores in C Kenya (S. Takata unpubl.). Remains have not been found in pellets of raptors, nor in snakes. Ectoparasite load is very low; the coarse spiny coat and social grooming probably facilitate removal of ticks and fleas.

Conservation IUCN Category: Least Concern.

Acomys russatus GOLDEN SPINY MOUSE

Fr. Souris épineuse dorée; Ger. Goldstachelmaus

Acomys russatus (Wagner, 1840). Abhandlungen der Bayerischen Akademie der Wissenschaften, Mathematisch-Naturwissenschaftliche Klasse 3: 195 (pl. 3, fig. 2). Probably Nohel, Sinai, Egypt.

Taxonomy Originally described in the genus *Mus*. This species occupies an inter-generic distant position, the 'russatus section' of Ellerman (1941), a view confirmed by Denys *et al.* (1994) on the basis of karyology and dentition characters. The cusps t1 and t2 of M¹ are well fused transversely and arranged in a laminate pattern. A related form, *lewisi*, considered to be a separate species by Atallah (1967) and Qumsiyeh *et al.* (1986) on the basis of colour and the morphology of the baculum, is now considered to be a synonym or subspecies of *A. russatus* (see Osborn & Helmy 1980, Harrison & Bates 1991, Musser & Carleton 2005). This view is supported by studies on mitochondrial DNA cytochrome *b* sequences (Barome *et al.* 2000). Synonyms: *aegyptiacus*, *affinis*, *harrisoni*, *lewisi*. Subspecies: none. Chromosome number: 2n = 66, FN = 76 (Wahrman & Zahavi 1953).

Description Large golden-brown spiny mouse with relatively short tail. Well-developed spines on most parts of body, including on feet. Dorsal pelage pale golden-brown or reddish-orange, slightly darkening on rump; spines pale grey at base, with broad orange or yellowish subterminal band and black tip. Scattered long, fine, white hairs project beyond the spines on posterior half of back. Flanks yellowish-brown. Ventral pelage whitish or yellowish; hairs grey at base. Colour of dorsal and ventral pelage weakly delineated on flanks; strongly delineated on cheeks and side of neck. Head similar in colour to dorsal pelage. Eyes with conspicuous white suborbital patch. Ears black, relatively small, covered with short buffy hairs; subauricular and postauricular white patches. Fore- and hindlimbs

grey. Undersurface of feet black. Tail relatively short (ca. 60% of HB), black and scaly, with relatively long silvery bristles projecting between scales. Nipples: 1 + 2 = 6.

Geographic Variation The form *aegyptiacus* from the Eastern Desert differs from *russatus* by having a pale reddish-orange dorsal pelage and a shorter tail.

Similar Species

A. cahirinus. Dorsal pelage blackish or brownish (never golden-brown); tail longer and relatively longer (ca. 90–100% of HB).

Distribution Sahara Arid BZ. Recorded in Eastern Desert of Egypt between the Nile R. and the Red Sea (from ca. 26° N to ca. 30° N), and in Sinai. Extraliminally in Jordan, Israel, Saudi Arabia, N Yemen and Oman (Harrison & Bates 1991).

Habitat Boulder-strewn canyons, cliffs and rocky hillsides in arid environments. Occasionally may occur in gardens around habitations. Altitudinal range: below sea level (Dead Sea; Atallah 1970) to ca. 2285 m (Mt Sinai).

Abundance Rare and localized in Egypt (Osborn & Helmy 1980), especially when compared with syntopic *A. cahirinus*. In Middle East, appears to be common in some localities, e.g. densities of 14–46/ha (mean 28/ha) during spring and summer in Israel (Shargal *et al.* 2000).

Adaptations Terrestrial and rupicolous. Nocturnal and diurnal. Golden Spiny Mice tend to be diurnal and crepuscular when syntopic with *A. cahirinus* (Shkolnik 1971) and in cold weather (Haim & Borut 1975). Although most habitats are hot and arid, some populations survive on the summit of Mt Sinai (Jebel Musa; 2200 and 2285 m), where there is snow and a mean temperature of below 0 °C in winter (Jan–Mar). Adaptations to the cold environment include larger body size than individuals at lower altitudes, diurnal and crepuscular activity when daytime temperatures are warmer, maintenance of a stable Tb of 35–37 °C, and by not entering torpor or hibernation (Haim & Borut 1975).

Diurnal activity (an unusual feature of small mammals in arid environments) may result in potentially higher water loss. Golden Spiny Mice are able to utilize salty water and extract water from halophytic plants, and additional water is obtained by eating desert snails (Shkolnik & Borut 1969).

Golden Spiny Mice adapt to the presence of syntopic *A. cahirinus* in several ways that are assumed to reduce competition, e.g. diurnal activity rather than nocturnal activity and larger body size. In competitive situations, *A. russatus* is displaced by *A. cahirinus* despite being larger than *A. cahirinus* (Shargal *et al.* 2000).

Acomys russatus

Foraging and Food Omnivorous. The diet is mainly seeds of herbs and grasses; desert snails, insects and their larvae are also eaten. Unable to survive on a dry diet alone (Harrison & Bates 1991).

Social and Reproductive Behaviour In Israel, mean home-range was 533 m² for ♂♂ and 668 m² for ♀♀ (n = 12 for each species; Shargal *et al.* 2000). Females construct nests for their young – a character not recorded for any other species of spiny mice (Searight 1987). Competition for nesting sites is subject to fierce competition due to the harsh conditions under which *A. russatus* exists. Urine and oral secretions are used to mark the home area, especially nesting sites (Rozenfeld *et al.* 1994).

Reproduction and Population Structure In Egypt, pregnant ♀♀ recorded only in May and Jun (Osborn & Helmy 1980). In the Dead Sea area of Israel, reproductive activities restricted to four months in late spring and early summer (Apr–Jul) (Qumsiyeh 1996, Shargal *et al.* 2000). In captivity, reproduction occurs throughout the year (Searight 1987). Gestation: 44 days. Litter-size: 1–2 in young ♀♀, up to four in older ♀♀ (Harrison & Bates 1991). Young are precocial at birth. Females mature very early, at about Day 31.

Predators, Parasites and Diseases Ectoparasites include the fleas *Parapulex chephrensis*, *Nosopsyllus geneatus* and *N. henleyi* (Hoogstraal & Traub 1965b) and various lice (Johnson 1960). Infection rate with

fleas is low; and most of the 40 *A. russatus* examined at St Catharine's Monastery in Sinai (5000 ft) were not infected (Hoogstraal & Traub 1965b).

Conservation IUCN Category: Least Concern. Although rare or uncommon in Egypt, the species is widespread and not uncommon in other parts of its geographic range.

Acomys spinosissimus LEAST SPINY MOUSE (SOUTHERN SPINY MOUSE)

Fr. Souris épineuse petite; Ger. Kleine Stachelmaus

Acomys spinosissimus Peters, 1852. Reise nach Mossambique, Säugethier, p. 160. Buio and Tette (= Tete), Mozambique.

Taxonomy Differences in size and colour have confused the taxonomy of this species. *Acomys spinosissimus*, as understood here, is a valid species with regional variation in pelage colouration. Southern grey-coloured individuals were originally described as *A. selousi*, the northern richer russet-coloured individuals as *A. spinosissimus*, and individuals intermediate in colour as *A. transvaalensis* (Dippenaar & Rautenbach 1986, Janecek *et al.* 1991). Populations from all parts of the range are considered as monophyletic, and quite distinct from species found further south (*A. subspinosus*) and further north (e.g. *A. wilsoni*, *A. ignitus*, *A. cahirinus*) (Barome *et al.* 2000). Synonyms: *selousi*, *transvaalensis*. Subspecies: none. Chromosome number: 2n = 60, FN = 68 (South Africa; Dippenaar & Rautenbach 1986).

Description Small mouse with spiny hairs on the back and rump. Dorsal pelage grey or fawn to bright russet-brown, but variable (see below). Hairs on shoulders and flanks soft and brush-like; hairs on rump and back thickened to form soft spines, pointing posteriorly and slightly longer than other hairs; hairs pale grey, white at base, and tipped with grey, fawn or russet. Hairs on flanks softer and paler than on back. Some individuals have patch-like pattern of grey and russet dorsal pelage. Ventral pelage pure white, without spines. Head similar in colour to back; chin and throat white; white spot below each eye. Ears naked, rounded and moderate in size; eyes large, black, protruding. Fore- and hindfeet white dorsally, naked and unpigmented below. Tail relatively long (ca. 80–90% HB), grey

or russet above, white below, almost naked. Males are, on average, slightly larger than ♀♀. Nipples: 0 + 2 = 4.

During the moult, faded old hairs are replaced by brighter and darker new hairs. The junction between old and new hairs as the moult proceeds from the rump to the head is very clear cut.

Geographic Variation Southern parts of range (South Africa, W Zimbabwe), dorsal pelage slate-grey, or grey with a tinge of brown. Northern part of range (E Zimbabwe, Mozambique, Malawi), dorsal pelage fawn, apricot, or russet brown. In Zimbabwe, Smithers & Wilson (1979) recognized three subspecies, now synonyms: *A. s. spinosissimus* (reddish-brown, east of range), *A. s. selousi* (west of range, greyish) and *A. s. transvaalensis* (centre of range, intermediate in colour).

Similar Species

A. subspinosus. Similar size; Cape region of South Africa only.

A. wilsoni. On average larger; spines very stiff; dorsal pelage bright cinnamon; distribution further north in Tanzania and Kenya; may be parapatric in C Tanzania.

Distribution Endemic to Africa. Zambezi Woodland BZ. Recorded from Tanzania and W Zambia through SE DR Congo, Malawi, C Mozambique, Zimbabwe, W Botswana and South Africa (Northern and North-West Provinces). May also occur in N

*Acomys spinosissimus*

Mozambique, parts of C Zimbabwe (lack of records perhaps due to inadequate collecting) and NE Tanzania (habitats perhaps unsuitable).

Habitat Least Spiny Mice almost always associated with rocks and boulders in grassland habitats. Less often, found in dry deciduous thicket-bush. In a few localities, have been found in sandy soil near rivers (Smithers & Lobão Tello 1976). Do not normally occur in riverine grasslands nor in miombo and mopane woodlands where boulders are absent. They can survive in habitats that have long hot dry seasons when there is no drinking water, and where the grass is burned each year.

Abundance Abundance (as a % of the small rodent community) varies greatly according to locality and habitat. In Zimbabwe, comprised 7.9% in talus habitats (where they were the second most numerous species after *Aethomys namaquensis*) and 3.6% in thickets (Linzey & Kesner 1997b); in Mozambique, 24% in rocky grasslands near a stream (Gliwicz 1985); and in Malawi, 24% in thicket clump savanna at Lengwe N. P. (total $n = 222$) and 46% in rocky savanna at Liwonde N. P. (total $n = 106$) (Happold & Happold 1990, 1991). In Zimbabwe, annual minimum and maximum densities range from 0/ha (dry season) to 4.2/ha (wet season) (Linzey & Kesner 1997a); in Malawi, from 2/ha to 16/ha in Liwonde N. P., and 4/ha to 19/ha in Lengwe N. P. (Happold & Happold 1990, 1991).

Adaptations Nocturnal and terrestrial. During the day, Least Spiny Mice hide under, and in the crevices of, boulders and rocks. The simple nest is made of leaves and dry grass. Despite their short limbs, they are very agile, running and climbing over rocks quickly and easily. They do not burrow, except to forage (see below). At certain times of year, there may be many months when free water is not available and survival depends on water in their food; conservation of water is likely to be as efficient as for *A. cahirinus*.

Foraging and Food Insectivorous and granivorous. In Malawi, 93% ($n = 44$) of stomachs contained insect remains (mostly beetles, but also ants, tipulid larvae, cockroaches) and diplopods (centipedes), and 45% contained vegetable material (mostly roots) (Hanney 1965, as *A. cahirinus*). In Mozambique, the diet (assessed by stomach content analysis) was 60% insects and 40% starchy material (fruits, seeds, bulbs), with an increase in insects (to 75%) in the dry season (Gliwicz 1987). Middens of 'feeding waste' consisting of small shells and the discarded fragments of beetles, bugs, ants, termites and spiders (Vesey-Fitzgerald 1966) have been observed in sheltered crannies of rocks in Tanzania, suggesting that spiny mice catch their prey and then carry it to a safe place to eat it. In Malawi, 'feeding tunnels' lead to roots, which are eaten by spiny mice.

Social and Reproductive Behaviour In captivity, several individuals can be kept together, which suggests that they are social animals. On one occasion, two spiny mice were captured in the same live-trap; on release, they ran into separate holes 1.5 m apart (D. C. D. Happold unpubl.).

Reproduction and Population Structure Reproductive characters probably similar to those of *A. cahirinus*. In Malawi, reproduction is seasonal. Most pregnancies and births occur during the wet season (Dec–Apr), although some ♀♀ may give birth during the early dry season (May) (Hanney 1965; Happold & Happold 1990, 1991). Mean embryo number: 3.2 (range 2–5, mode 3 and 4, $n = 17$); however, number of embryos increases with size of mother: mean 2.9 for ♀♀ with HB = 80–97 mm ($n = 9$), and 3.6 for ♀♀ with HB >97 mm ($n = 7$). Largest, oldest ♀♀ produce nine young (= three litters) in a breeding season (Hanney 1965). Young are large and precocial at birth, and nipple-dragged by mother until Day 12; young weaned at Day 26.

In Malawi (Happold & Happold 1991), at end of the dry season (Sep–Oct), population numbers are small, mostly subadults plus a few old adults. At beginning of the wet season, subadults become adult, reproduction commences and the first young enter population. By end of the wet season and beginning of the dry season (Mar–Jun), all old adults have died, populations are mainly composed of young and subadults, and populations reach their peak (about ×3 minimum numbers). Longevity in the wild not more than 12 months.

Predators, Parasites and Diseases Rarely preyed upon by Barn Owls *Tyto alba* in Malawi (Hanney 1962). Ectoparasites include two species of fleas and one species of louse (Hanney 1965).

Conservation IUCN Category: Least Concern.

This widespread species is not threatened at present.

Acomys subspinosus CAPE SPINY MOUSE

Fr. Souris épineuse du Cap; Ger. Kap-Stachelmaus

Acomys subspinosus (Waterhouse, 1838). Proc. Zool. Soc. Lond. 1837: 104. (publ 1838).

Cape of Good Hope, South Africa (= Table Mountain, Cape Town: Roberts 1951).

Taxonomy Originally described in genus *Mus*. The name *subspinosus* was originally used only for southern Cape population of *Acomys*; later some northern populations from southern Africa were also ascribed to *A. subspinosus* (Setzer 1975). Subsequent morphometric and karyotypic analyses confirm that *A. subspinosus* is restricted to the South-West Cape BZ, and that it is distinguished from *A. spinosissimus* in the north of southern Africa by its narrow teeth and reduced M³ (Dippenaar & Rautenbach 1986). Separation from other *Acomys* is indicated by phylogenetic analyses of mtDNA cytochrome *b* sequences (Barome *et al.* 2000). Synonyms: none. Chromosome number: 2n = 60, FN = 70 (Dippenaar & Rautenbach 1986).

Description Small spiny mouse with pale underparts, darker dorsal surface and distinctive bristle-like hairs. Dorsal pelage rust-brown to dark greyish-brown, flanks and outer surface of limbs paler. Ventral pelage and inside of limbs dirty white; hairs pure white. Clear delineation in colour between flanks and ventral pelage. Head narrow, with pointed nose, long vibrissae; sides of muzzle white. Medium-sized ears, light flesh colour on inner surface, dark brown on outer surface. Fore- and hindfeet white to dirty white above, yellowish-brown to brown below; five digits on each foot, Digit 5 on forefoot reduced to a small stump with a nail rather than a claw. Tail moderately long (ca. 95% of HB), stout, covered with short brown to dark greyish-brown bristles above, yellowish to whitish below. Skull with relatively broad, rounded braincase, and very short maxillary and mandibular toothrows; narrow teeth and reduced M³. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species This species is the only species of *Acomys* in the South-West Cape BZ.

Distribution Endemic to Africa. South-West Cape BZ. Disjunct populations in S and SW of Western Cape Province, South Africa, from Citrusdal in the west to Knysna in the east, extending northwards into Namaqualand (Dippenaar & Rautenbach 1986). Present on the Cederberg Mts, Table Mountain, Swartberg, Outeniqua and Kammanassie Mts; and rocky slopes and ledges around Nieuwoudtville.

Habitat Rocky mountainous habitat, rocky slopes and ledges.

Abundance Varies from 0.9/ha to 13.7/ha in suitable habitat (Fleming & Nicolson 2002a).

Adaptations Nocturnal and terrestrial. Moves by quadrupedal running and walking. Physiological adaptations permit survival during cold temperate winter rainfall. At low ambient temperatures, Cape Spiny Mice utilize body reserves to generate heat, and are not homeothermic. Evaporative water loss is high, compromising survival in a water-scarce environment. Thermal conductance rises sharply above thermoneutral zone, indicating that the spiny pelage may facilitate heat loss at high ambient temperatures (Perrin & Downs 1994).

Foraging and Food Cape Spiny Mice feed almost exclusively on seeds (91–94%), as well as small amounts of green plant material and insects (Nel *et al.* 1980). Pollen from *Protea humiflora* comprised up to 80% of scats collected during winter months in a study conducted in Riviersonderend Mts. Cape Spiny Mice contribute significantly to pollination and seed-set in *P. humiflora* (Fleming & Nicolson 2002a).

Social and Reproductive Behaviour No information available.

Reproduction and Population Structure Juveniles and pregnant ♀♀ found throughout the year, with peaks in breeding in

some populations (Fleming & Nicolson 2002b). Breeding probably opportunistic, depending on resource availability. Gestation: >27 days. Mean litter-size: 3. Mean birth-weight: 3.3 g. Growth rate in first 28 days: 0.55 g/day. Young are altricial and do not nipple-cling. Hair visible Day 1–2, incisors erupt Day 7; eyes open Days 9–10 (Dempster *et al.* 1992).

Predators, Parasites and Diseases No information available.

Conservation IUCN Category: Least Concern.

Acomys wilsoni WILSON'S SPINY MOUSE

Fr. Souris épineuse de Wilson; Ger. Wilsons Stachelmaus

Acomys wilsoni Thomas, 1892. Ann. Mag. Nat. Hist., ser. 6, 10: 22. Mombasa, Kenya.

Taxonomy Formerly included in *A. subspinosus* (Setzer 1975). Genetically most closely related to *A. percivali* (Janacek *et al.* 1991). Synonyms: *ablutus*, *argillaceus*, *boronei*, *enid*, *nubilus*. Subspecies: none. Chromosome number: 2n = 50 (Matthey 1968).

Description Small chestnut or brownish spiny mouse. Pelage coarse and stiff with strong spines (ca. 5 mm) from mid-back to base of tail and on rump. Dorsal pelage bright cinnamon or chestnut to olive-brown, sometimes darker on mid-dorsal line, and with a 'speckled' appearance; hairs/spines pale grey at base with chestnut, cinnamon or brown terminal band, and black tip. Colour varies geographically (see below). Ventral pelage pure white. Colour of ventral pelage clearly delineated from colour of flanks. Head similar in colour to dorsal pelage. Small white suborbital spot. Ears pigmented (pale or dark), sparsely covered with small hairs. Subauricular and postauricular spots present in some individuals. Chin, throat and chest white. Limbs short. Fore- and hindfeet white. Tail relatively long (ca. 94% of HB), slightly scaly, almost naked but with scattered short bristles; pale brown or whitish above, white below. Tail often absent or short due to injury. Nipples: not known.

Geographic Variation Colour of dorsal pelage varies geographically: bright chestnut (N Kenya), brown speckled with buff (*argillaceus*; Sudan, N Kenya), or brownish-cinnamon and not speckled (Uganda).

Similar Species

A. percivali. Similar size; dorsal pelage grey; strong spines on mid-dorsal region; tail on average shorter (mean 73 mm) and relatively shorter (ca. 76% of HB); frequently syntopic; often very common.

A. kempi. Similar head and body size; dorsal pelage orange-buff, flanks dull orange; stiff spines on mid-back; tail on average longer (mean 93 mm) and relatively longer (ca. 94% of HB); distribution restricted.

A. ignitis. Similar head and body size; dorsal pelage brownish-orange, with bright reddish-orange flanks; tail probably shorter, and relatively shorter (77% of HB); restricted to low altitudes in SE Kenya and N Tanzania.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from S Sudan, S Ethiopia, NE Uganda, S Somalia, Kenya and S to C Tanzania. Limits of distribution uncertain.

Habitat Rocky habitats, where coexist with *A. percivali* in C Kenya. Also found in grasslands where there is dense shrubby vegetation cover. Occasionally, individuals inhabit houses. In its choice of habitat, this species is more opportunistic than sympatric *A. percivali*.

Acomys wilsoni

Abundance Common in preferred habitats, although distribution is localized and patchy.

Adaptations Nocturnal, terrestrial and arboreal/scansorial. Excellent climbers on rocky outcrops and on trees. Similar in many respects to *A. percivali*.

Foraging and Food Omnivorous, mainly insectivorous. Diet varies seasonally. In the dry season, the diet comprises 60–95% arthropods and <5% stems and leaves and 5–40% seeds; in the wet season, 65–90% arthropods, 0–5% stems and leaves and 10–30% seeds; and in the intermediate seasons (between wet and dry) 35–55% arthropods, 0–15% stems and leaves and 45–50% seeds (Neal 1984a). In cafeteria-style feeding trials, wild-caught mice fed almost exclusively on insects (S. Takata unpubl.).

Social and Reproductive Behaviour Little information. In captivity, individuals are very tolerant of other adults of either sex and, unlike Percival's Spiny Mice, are not aggressive in captive colonies, even at high densities. Trapping in Kenya shows that adults have widely overlapping home-ranges; when caught in the same trap, two adults seem tolerant of one another.

Reproduction and Population Structure Breeding activity occurs throughout the year, with 60–100% of adult ♀♀ pregnant in all months except Mar (Neal 1983) and is similar to that of sympatric *A. percivali*. Wilson's Spiny Mice are prolific breeders, mainly because of continuous reproduction and the short interval between litters. Gestation: 4–6 weeks (S. Takata unpubl.). Mean interval between litters: 46.3 days (Neal 1983). Litter-size: 2 (no range recorded) (S. Takata unpubl.). Embryo number: 2.2 ± 0.09 ($n = 79$ pregnancies; Neal 1983); 1–3 ($n = 4$; Delany 1964a). Estimate of 7.9 litters/female/year and annual production of 17.4 young/female/year (Neal 1983). Larger older ♀♀ have larger litters (mean = 2.41) than smaller ♀♀ (mean = 1.97) (Neal 1983). At birth, young are precocious; weight = 3–4 g (wild-caught; Neal 1983); 5 g (in

captivity; S. Takata unpubl.). Weight at weaning 10 g, at puberty 10–13 g (♂♂) and 10–15 g (♀♀), adult size ca. 17 g.

There is little seasonal change in the structure of the population (as assessed by wear of molar teeth). Young, adult and old individuals are present in most months, with a reduction in the number of older animals in Jan–Jun (Neal 1983).

Predators, Parasites and Diseases Remains have not been found in faecal samples of mongooses and genets, even in areas where the mice are common. Like Percival's Spiny Mice, Wilson's Spiny Mice do not carry heavy loads of ectoparasites in the wild (S. Takata unpubl.).

Conservation IUCN Category: Least Concern.

GENUS *Deomys*

Rusty Link Rat

Deomys Thomas, 1888. Proc. Zool. Soc. Lond. 1888: 130. Type species: *Deomys ferrugineus* Thomas, 1888.

Deomys is a monotypic genus restricted to the Rainforest BZ in the Congo Basin from S Cameroon to Uganda.

This genus is easily distinguished by a combination of diverse external characters, including its reddish coarse-textured pelage, long, pointed muzzle, large oval ears, pure white ventral pelage and musky shrew-like odour. Unique skull characters are the long tapered rostrum, sharply pointed and widely spaced cusps on the first two molars (somewhat reminiscent of the cusps on the molar teeth of a shrew), M¹ longer than M² + M³, M³ reduced, and the absence of zygomatic plates (Figure 41).

Although historically *Deomys* has been classified under the subfamily Dendromurinae, its morphological characters are not consistent

with that subfamily (see Rosevear 1969). More recently, genetical and molecular analyses consistently placed *Deomys* in the same clade as *Acomys*, *Lophuromys* and *Uranomys* (Musser & Carleton 2005 and references therein). However, dental characters are not those of these acomyine rodents (Denys *et al.* 1995) and sperm morphology is not that of the Dendromurinae nor the *Acomys/Uranomys* group (Breed 1995). The genus appears to be an isolated lineage, and is currently placed in the subfamily Deomyinae (see subfamily profile and Musser & Carleton 2005).

J. C. Ray & J. R. Malcolm

Figure 41. Skull and mandible of *Deomys ferrugineus* (BMNH 38.444).

Deomys ferrugineus.

Deomys ferrugineus RUSTY LINK RAT (CONGO FOREST RAT)

Fr. Rat à manteau roux; Ger. Deomys-Waldmaus

Deomys ferrugineus Thomas, 1888. Proc. Zool. Soc. Lond. 1888: 130. Lower Congo.

Taxonomy Synonyms: *christyi*, *poensis*, *vandenberghiei*. Subspecies: none. Chromosome number: not known.

Description Medium-sized rat with rich reddish-brown coarse-textured pelage and very long tail. Dorsal pelage reddish-brown; hairs pale white or silvery-grey at base, brown at tip. Hairs on mid-back and rump coarse and stiff, darker due to many black-tipped hairs. Ventral pelage pure white and sharply delineated from flanks. Head narrow with very long, pointed muzzle and long vibrissae. Large oval ears, appear naked but sparsely covered with very short hairs. Head similar in colour to back, with blackish band across muzzle in front of eyes. Nasal region and cheeks cinnamon. Chin, throat, chest and inner surface of hindlimbs white. Feet very long, covered in short white hairs and with five prominent subconical pads on soles. Hindfoot with five digits, Digits 2, 3 and 4 long; Digit 1 very short, Digit 5 short. Tail very long (ca. 140% HB), scaly, distinctly bicoloured (dark above and white below); covered with short bristles basally, with longer hairs terminally. Distinct, musky, shrew-like odour. Skull: elongated and flattish, long tapered rostrum, zygomatic plate absent; each upper incisor with groove close to inner edge; sharply pointed and widely spaced cusps on the first upper two molars, M^1 longer than $M^2 + M^3$; M^3 reduced. Nipples: $0 + 2 = 4$.

Geographic Variation Colour of dorsal pelage varies geographically, from reddish-brown (mainland Africa) to dark brown (Bioko I.; *poensis*).

Similar Species

Colomys goslingi. White ventral pelage woolly in texture; ears smaller and rounder; and Digit 5 on hindfoot longer.

Malacomys longipes. Dorsal pelage darker with velvet-like texture, ventral pelage whitish-grey and never pure white; ears rounder; hindfeet on average longer.

Distribution Endemic to Africa. Rainforest BZ (East Central Region and parts of West Central Region). Recorded from Cameroon Mountain and Benito R. (Rio Muni, Equatorial Guinea) to E DR Congo, W Uganda and Rwanda. Present on Bioko I. Not present in West Africa or in DR Congo south of the Congo R.

Habitat One of the few true African forest species (Rosevear 1969). Generally confined to deeper regions of virgin forest (Sanderson 1940), although Hatt (1940a) recorded it in more disturbed areas on forest edges and in farms. At Irangi, E DR Congo, all but two (of 35) individuals were captured in 'primary' forest on hills (Rahm 1972). Trapping over two-year period in logged forests of SW Central African Republic revealed that this species generally avoids disturbed habitats along logging roads. Preferred habitat (assessed by high abundance) was characterized by a low and sparse understorey, low density of saplings and closed canopy (Ray 1996, Malcolm & Ray 2000); and in NE Gabon, preferred habitat was in tree-fall gaps

*Deomys ferrugineus*

where there were particularly high amounts of fallen and dead woody debris (Duplantier 1989). Recorded at altitudes from near sea level to 6500 ft; may be particularly fond of montane forest above 1500 ft (Rosevear 1969). Delany (1975) and Kingdon (1974) reported a strong association with water in Uganda (as did Sanderson [1940] in Cameroon), but Ray (1996) captured few individuals close to streams in Central African Republic. Kingdon (1974) suggested that *Deomys* may fill the niche of the stream-dependent *Malacomys longipes* where that species is absent.

Abundance Represented 7% of total catch ($n = 3541$) at Irangi, DR Congo where 60–70% of specimens of *D. ferrugineus* were captured in primary forest habitats (Dieterlen 1985b). In SW Central African Republic comprised 11.1% of all captures ($n = 458$) from unlogged mixed-species forest, 3.7% from monodominant *Gilbertiodendron dewevrei* forest ($n = 406$), 1.1% along secondary logging roads ($n = 704$) and 0.5% along streams ($n = 200$) (Ray 1996). During six trapping sessions in undisturbed forest at Makokou, Gabon, relative abundance ranged from 1.3% to 12.6% (mean 11.1%, $n = 549$). Density at Makokou was 0.2–1.2 individuals/ha (Duplantier 1989).

Adaptations Nocturnal (Rahm 1967, Genest-Villard 1980, Kerbis Peterhans & Patterson 1995) and/or crepuscular (Sanderson 1940; Kingdon 1974). Narrow stilt-like hindfeet for wading in shallow water (Delany 1975; Kerbis Peterhans & Patterson 1995). Strictly terrestrial (Genest-Villard 1980, Malcolm & Ray 2000). Nests made of leaves and vegetable matter, located in holes at the base of trees (Rosevear 1969). Acutely cusped teeth adapted for

insectivorous diet (Rosevear 1969). The large infraorbital foramen, wedge-shaped cuspidation of the molar teeth, and the movements of the mandible so that different cusps can inter-digitate, are probably adaptations associated with the insectivorous diet (Lemire 1966).

Foraging and Food Predominantly insectivorous. Forages in leaf litter for ants, termites, grasshoppers, beetles, cockroaches, fly larvae, caterpillars, millipedes and centipedes (Rosevear 1969, Duplantier 1982). Of 15 stomachs collected by Rahm (1972), 11 (73.3%) contained insects only, two (13.3%) contained a mixture of insects and vegetable matter, and the remainder contained vegetable matter only. Nearly 100% of 29 stomachs from Makokou (Gabon) contained insects; remains of seeds, gastropods, earthworms, reptiles and rodents also present (Duplantier 1982). Hatt (1940a) also reported rodent flesh in one stomach from DR Congo. Insects were also the main component of the diet at Mbaiki (Central African Republic), although vegetable matter comprised 17–26% (Genest-Villard 1980). Living prey is pounced upon and attacked using the incisor teeth, then held down and torn apart (Kingdon 1974).

Social and Reproductive Behaviour Solitary or in pairs or with young; possibly territorial (Rosevear 1969, Delany 1975). In Makokou (Gabon), home-ranges of ♂♂ ($5467 \pm 160 \text{ m}^2$, $n = 3$) are significantly larger than for ♀♀ ($2533 \pm 874 \text{ m}^2$, $n = 6$). Maximum recapture distance for ♂♂ averaged 102.4 m ($n = 11$), and for ♀♀ 48.2 m ($n = 11$) (Duplantier 1982).

Reproduction and Population Structure Reproductively active for 95% of the year at Irangi, DR Congo – a situation seen in mainly insectivorous rodents whose main source of nutrition is abundant throughout the year (Dieterlen 1985a, 1986). Litter-size varies according to locality: 1.8 (1–2, $n = 25$; Dzanga-Sangha, Central African Republic; J. C. Ray & J. R. Malcolm unpubl.); 1.69 (1–4, $n = 67$; Irangi, DR Congo; Dieterlen 1985a); 3.0 (3–3, $n = 3$; Makokou, Gabon; Dubost 1968). The greatest proportion of ♀♀ were reproductively active during wet seasons in Dzanga-Sangha although the trend not as pronounced as for other species in the

same community (Ray 1996). Average body weights did not vary significantly between seasons or between two years (Ray 1996).

Predators, Parasites and Diseases Small carnivores from Dzanga-Sangha were found to prey selectively on this species, probably because all of them frequent the same micro-habitats while foraging for termites and other invertebrates (Ray 1998).

Conservation IUCN Category: Least Concern.

Close association with undisturbed forests, and general absence from secondary forests, means that deforestation and degradation of forests by logging and agricultural clearing are potential threats.

Measurements

Deomys ferrugineus

HB (♂♂): 131.0 (109–150) mm, $n = 46$

GENUS *Lophuromys*

Brush-furred Rats

Lophuromys Peters, 1874. Monatsber. K. Preuss. Akad. Wiss. Berlin, p. 234.

Type species: *Lasiomys afer* Peters, 1866 (= *Mus sikapusi* Temminck, 1853).

The genus *Lophuromys* contains 15 species, widely distributed throughout tropical Africa. Preferred habitats of most species include moist grasslands, swamps and marshes, agricultural fields and abandoned farmlands provided there is dense cover and soft soil. They are rare in primary and secondary rainforest except where there are grassy patches. Distribution ranges from about 15°S to 15°N, and from near sea level to ca. 4500 m. Most species are endemic to isolated mountain regions; others (*L. flavopunctatus*, *L. sikapusi*, *L. nudicaudus*, *L. huttereri*) have larger geographic distributions.

Species within the genus have harsh to soft rufous, rusty or olive-coloured brush-like hairs, especially on the back and flanks (similar to those in the genus *Uranomys*, but not as thick or spiny as in *Acomys*).

The dorsal pelage may be 'speckled' (due to a scattering of pale-tipped hairs) or 'unspeckled'. They have small eyes, pointed muzzles, short limbs, long or short curved claws, and most species have a comparatively short hairless tail (which is often partially lost due to damage). The skull is rather slender, with small incisors, weak interorbital constriction and in most species the zygomatic plate is much reduced in width and cut away above (Figure 42).

They are exclusively terrestrial – most species are rather heavily built with short limbs, which makes climbing virtually impossible. Typically, locomotion is by running over the surface of the ground, and by pushing through and under litter and decaying vegetation; grass nests are constructed amongst litter and grass tussocks. They

Lophuromys flavopunctatus.

do not dig burrows. Activity is mostly diurnal and crepuscular. Brush-furred mice are omnivorous, and include a large proportion of insects and other invertebrates in the diet. Reproduction is seasonal, the young are rather precocial and litter-size is small (normally 1–3). A unique feature of the genus is the presence of a large gland on the undersurface of the stomach, which is associated with digestion, although its function is uncertain (Genest-Villard 1968, 1980; Dieterlen 1976b).

Ellerman (1941) and Misonne (1969a) considered *Lophuromys* as a ‘specialized and distinct offshoot’, an isolated group among the African Muridae, a view confirmed by Dieterlen (1976b), Denys & Michaux (1992) and W. Verheyen *et al.* (1996). Traditionally *Lophuromys* has been placed in the subfamily Murinae (e.g. Musser & Carleton 1993). However, non-morphological evidence (DNA/DNA hybridization experiments, mitochondrial RNA, amino-acid sequences, etc.) link *Lophuromys* with *Acomys*, *Uranomys* and *Deomys* in a monophyletic clade that is distinct from the Murinae. Here, following Musser & Carleton (2005), the genus is placed with these genera in the Deomyinae (see also profile Subfamily Deomyinae).

Despite its clear generic characters, the genus is considered to comprise three species-groups: (a) the ‘*sikapusi* species-group’, with short tail, short hindfoot and unspeckled pelage (*L. sikapusi* [including *ansorgei* and *angolensis*], *L. nudicaudus*, *L. hutcheri*, *L. roseveari*), (b) the ‘*flavopunctatus* species-group’, with short tail, short hindfoot and speckled pelage (*L. flavopunctatus*, *L. cinereus*, *L. brevicaudus*, *L. chrysopus*, *L. melanonyx*) or mainly unspeckled pelage (*L. dieterleni* and *L. eisentrauti*, as well as *L. rahmi*, which has slight speckling) and (c) the ‘*woosnami* species-group’ with long tail and long hindfoot and unspeckled pelage (*L. woosnami*, *L. luteogaster*, *L. medicaudatus*) (Dieterlen 1976b, Verheyen *et al.* 1986). An alternative arrangement

Figure 42. Skull and mandible of *Lophuromys sikapusi* (HC 1742).

(Dieterlen 1987) is division of the genus into two subgenera, *L. (Lophuromys)*, which represents all the short-tailed species (tail length 50–70% of HB) and *L. (Kivumys)*, which represents the three long-tailed species (tail length 85–105% of HB) of the ‘woosnami species-group’.

The taxonomy of the genus is controversial. Here, we profile 15 species (Table 20). In contrast, Musser & Carleton (2005) recognize 21 species including five that are treated here as synonyms. These are *L. zena* (Aberdare Range and Mt Kenya), *L. aquilus* (very widespread) and *L. brunneus* (S Ethiopia) which are treated here as synonyms of *L. flavopunctatus*; and *L. angolensis* (SW DR Congo) and *L. ansorgei* (eastern Africa) which are treated here as synonyms of *L. sikapusi*. Musser & Carleton (2005) also recognise two new species, *L. dudui* and *L. verhageni*, described on the basis of craniometric data and univariate analysis, by Verheyen *et al.* (2002). Musser & Carleton (2005) treat *L. cinereus* (profiled here as a valid species) as a synonym of *L. aquilus*.

The species can be distinguished by pelage colour and pattern, length of hindfoot, length of tail, cranial characters and by geographic location (Table 20).

Fritz Dieterlen

Table 20. Species in the genus *Lophuromys*. Arranged in order of species-group, and whether pelage is speckled or unspeckled.

| Species | Species-group ^a | Pelage speckled or unspeckled ^b | Tail ^c | Dorsal pelage | Ventral pelage | HB mean (range) (mm) | HF mean (range) (mm) | |
|----------------------------------|----------------------------|--|-------------------|---------------------------------|---------------------------------|----------------------|----------------------|--|
| <i>L. brevicaudus</i> | Fl | Sp | S | Grey, dull | Grey, cream | 114 (96–134) | 20.8 (19–22) | |

| <i>L. medicaudatus</i> | Wo | Usp | M | Dark olive-brown | Dark orange tinged with olive | 103 (92–112) | 20.8 (18–23) | |
| <i>L. woosnami</i> | Wo | Usp | L | Brown, tinged with olive-grey | Pale brown tinged reddish | 121 (111–135) | 26.5 (25–27) | |

^a Fl = *flavopunctatus* species-group (speckled pelage [most species], short tail, short hindfoot); Si = *sikapusi* species-group (unspeckled pelage, short tail, short hindfoot); Wo = *woosnami* species-group (unspeckled pelage, long tail, long hindfoot).

^b Sp = speckled pelage; Usp = unspeckled pelage.

^c S = short tail (50–70% of HB), M = medium tail (ca. 85% of HB), L = long tail (100–105% of HB).

^d External characteristics similar to *L. nudicaudus* (see profile).

Lophuromys brevicaudus SHORT-TAILED BRUSH-FURRED RAT

Fr. Souris hérissé à queue court; Ger. Kurzschwanz-Bürstenfellratte

Lophuromys brevicaudus Osgood, 1936. Zool. Ser. Field Mus. Nat. Hist. 20 (21): 241. Mt Albasso (= Mt Badda), Ethiopia.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. One of three Ethiopian endemic species of *Lophuromys*. Considered to be a synonym of *L. flavopunctatus* by Yalden *et al.* (1976). Allozyme, chromosomal and morphometric studies indicate that *L. brevicaudus* should be considered as a full species within the '*flavopunctatus* species-group' (Aniskin *et al.* 1997a, Lavrenchenko *et al.* 1997, 1998b). A very high level of genetic (allozyme) differentiation among populations from the Bale Mts is probably the result of isolation of local populations during Pleistocene glaciations (Lavrenchenko *et al.* 2000, Milishnikov *et al.* 2000). Synonyms: none. Chromosome number: 2n = 68 (the same as for *L. flavopunctatus sensu stricto*; Aniskin *et al.* 1997a, Lavrenchenko *et al.* 1997).

Description Small 'speckled' rat with relatively short tail. Dorsal pelage softer, shorter and generally duller than in other species of the *flavopunctatus* species-complex. Dorsal pelage dull grey; hairs grey at base with pale yellow subterminal band and black tip. Ventral pelage greyish, sometimes cream or yellowish; hairs dark grey at base, with

white tip (as in *L. melanonyx*). Underfur of dorsal and ventral pelage pale grey. Head dull grey, chin and throat grey with fewer white-tipped hairs than ventral pelage. Reddish-orange collar in some individuals, contrasting strongly with colour of chin and ventral region. Dorsal surface of forefeet blackish; dorsal surface of hindfeet grey with blackish central longitudinal band. Claws pale, longer than in other Ethiopian representatives of the '*flavopunctatus* species-group', especially on the forefeet. Tail short (ca. 50% of HB), grey, with scales and short black hairs above, whitish hairs below. Skull with unusually large auditory bullae medially close to each other. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

L. chrysopus. Tail relatively longer, greyish-rufous hindfoot with blackish toes; shorter claws; wider rostrum and skull base; more slender M¹ and more widely separated smaller auditory bullae.

| | Claw length and colour | Nipples | Notes |
|--|-----------------------------|------------------------|---|
| | Long, pale | 2 + 1 = 6 | Ethiopia only. 2n = 68 |
| | Short, pale | 2 + 1 = 6 | Ethiopia only. 2n = 54 |
| | Long, pale | 2 + 1 = 6 | Kivu Province, DR Congo; pelage grey |
| | n. d. | not known | W Cameroon only; small size |
| | Long, dark | 2 + 1 = 6
1 + 1 = 4 | Widespread. East and central Africa.
2n = 68 or 70 |
| | Long, black | 0 + 2 = 4 | Ethiopia only; largest sp. in genus. 2n = 60 |
| | n. d. | Not known | Mt Oku, Cameroon; pelage long |
| | Short-medium, pale or brown | Not known | E DR Congo and Rwanda; pelage rather harsh; small size |
| | Long, brown | Not known | C DR Congo. External characters similar to <i>L. nudicaudus</i> |
| | Long, brown | 2 + 1 = 6 | Central African rainforests; pelage very harsh; small size. 2n = 56 (polymorphic) |
| | Very long, brown | 2 + 1 = 6
1 + 1 = 4 | Mt Cameroon; pelage long |
| | Long, dark | 1 + 1 = 4 | Widespread in West and central Africa; pelage soft. 2n = 60 or 64 |
| | Short, pale | 2 + 1 = 6 | NE and E DR Congo; pelage harsh |
| | Short, pale | 2 + 1 = 6 | E DR Congo and Rwanda; montane; pelage harsh |
| | Short, pale | 1 + 1 = 4 | Mountains of Albertine Rift Valley; pelage soft; long HF. 2n = 42 |

L. flavopunctatus. On average larger and darker; relatively shorter claws, relatively smaller auditory bullae.

L. melanonyx. On average much larger and paler, black claws; tough skin (unusual in *Lophuromys*).

Distribution Endemic to Africa Afromontane–Afroalpine BZ of Ethiopia only. Confined to the western (Bonke) and eastern (Chilalo, Gedeb and Bale Mountains) high plateaux, from 2400 to 3750 m (Lavrenchenko *et al.* 1998b).

Habitat Afroalpine grasslands and *Erica* bush especially on mesa tops (Sillero-Zubiri *et al.* 1995a, Lavrenchenko *et al.* 1998b). Occurs also (in smaller numbers) in montane forest (Lavrenchenko *et al.* 1998b).

Abundance Numerous in suitable habitats; comprised 51% (n = 229 small mammals) trapped in the ericaceous zone of the Bale Mts (L. Lavrenchenko unpubl.).

Adaptations Diurnal and nocturnal; 50% of 80 captures occurred in the morning, 29% during the afternoon and 21% during the night in the Bale Mts (Sillero-Zubiri *et al.* 1995a). Long claws are presumed to be adaptations for burrowing. The relatively short tail might be an adaptation to the cold at high altitudes.

Foraging and Food Morphological studies show that the gastro-intestinal tract is intermediate in structure between that of *Aethomys* and *Mastomys* suggesting that the diet is mainly vegetable material (see also *L. chrysopus*). In this respect, this species differs

Lophuromys brevicaudus

from most other species of *Lophuromys*, which are insectivorous (L. Lavrenchenko unpubl.).

Social and Reproductive Behaviour Peaceful and un-aggressive. In captivity, neither ♂♂ nor ♀♀ demonstrate any

elements of agonistic behaviour towards conspecifics or parapatric *L. chrysopus*.

Reproduction and Population Structure Females collected in the Bale Mts during the late dry season and beginning of the wet season (Apr and May) were pregnant. Mean embryo number: 2.38 ± 0.18 (range 2–3; $n = 8$ pregnant ♀ ♀). Sex ratio close to unity.

Predators, Parasites and Diseases Little information. A few may be preyed upon by Abyssinian Long-eared Owls (*Asio abyssinicus*) (Yalden 1973). Not eaten by Simien Wolves (*Canis simensis*) (Sillero-Zubiri & Gottelli 1995).

Conservation IUCN Category: Near Threatened.

Abundant where found, but geographic range is very limited. Protected by the proposed Bale Mountains N. P.

Lophuromys chrysopus GOLDEN-FOOTED BRUSH-FURRED RAT (ETHIOPIAN FOREST BRUSH-FURRED RAT)

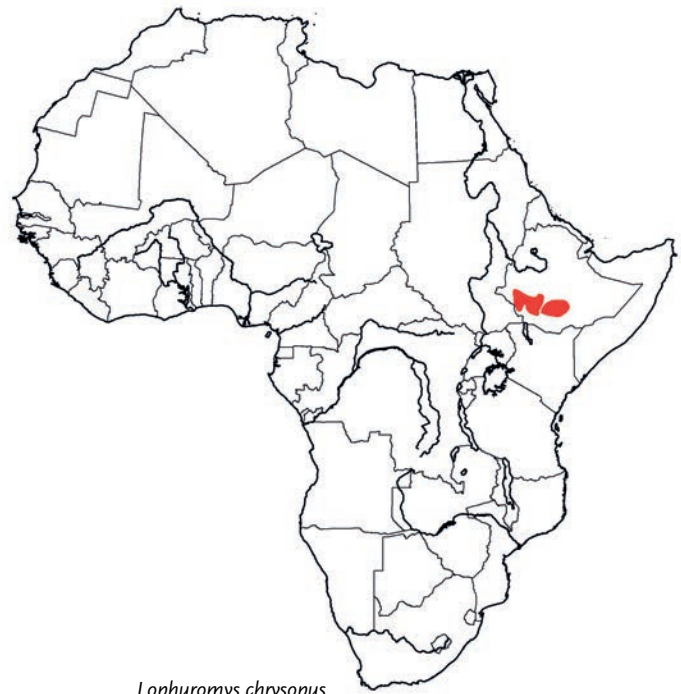

Fr. Souris hérissé à pieds d'or; Ger. Goldfüssige Bürstenfellratte

Lophuromys chrysopus Osgood, 1936. Zool. Ser. Field Mus. Nat. Hist. 20 (21): 242. Allata, Ethiopia.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. One of three endemic species of *Lophuromys* in Ethiopia. Considered as synonym of *L. flavopunctatus* (as *L. aquilus chrysopus*) by Yalden *et al.* (1976). Phylogenetic analyses (allozyme and RAPD) suggest that *chrysopus* is a rather recent and the most advanced derivative of the *flavopunctatus* species-group (Lavrenchenko *et al.* 2000, 2001), and separate from *L. flavopunctatus* and *L. brevicaudus*. Synonyms: none. Chromosome number: $2n = 54$ (Aniskin *et al.* 1997a, Lavrenchenko *et al.* 1997); a very high proportion of individuals (83%) in Beletta Forest possess supernumerary B chromosomes (2–6) (L. Lavrenchenko unpubl.).

Description Small 'speckled' rat with a relatively long tail. Pelage long (11–12 mm on mid-dorsal line), dense and slightly stiff. Dorsal pelage blackish-brown; hairs reddish-brown at base, black on distal half with pale yellow subterminal bands and black tip. Ventral pelage speckled, pinkish-cream to greyish-cream. Head similar in colour to dorsal pelage. Upper surface of forefeet blackish; upper surface of hindfeet greyish-rufous. Toes black. Claws pale, shorter, especially on forefeet, than in other Ethiopian representatives of this species-group. Tail relatively short (ca. 70% of HB), upper surface densely covered with grey or black scales and short black hairs; lower surface with pale grey scales and short dark grey hairs with white tips. Skull similar in size to *L. brevicaudus* but with wider rostrum and skull base, more slender M^1 and somewhat smaller and more widely separated auditory bullae. Nipples: $2 + 1 = 6$.

Geographic Variation Populations on either side of the Rift Valley differ in colour (Lavrenchenko *et al.* 1998). Dorsal hairs of individuals from west of the Rift Valley (Beletta Forest) are pale red on basal half, black on terminal half with pale tips, and ventral pelage is pale pink to reddish. Dorsal hairs of individuals from east of the Rift Valley (Hareenna Forest, Bale Mts) are bright red on basal half, black on terminal half with pale tips, and ventral pelage is yellow to pale orange.

Lophuromys chrysopus

Similar Species

L. brevicaudus. Shorter tail, grey hindfeet with black band, longer claws, larger auditory bullae.

L. flavopunctatus. On average larger size, relatively shorter tail, grey hindfeet with black band, longer claws (Lavrenchenko *et al.* 1998b).

L. melanonyx. On average much larger and paler, black claws: tough skin.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Widespread in montane forests (1200 to 2760 m) of the Ethiopian Highlands on both sides of the Ethiopian Rift Valley.

Habitat Afromontane forests. Does not occur in afroalpine grasslands and *Erica* bush (cf. *L. brevicaudus*).

Abundance One of the commonest rodents in Ethiopian montane forests. Comprised 32% (n = 153 small rodents) caught in the Haremma Forest, and the second most numerous species after *Stenocephalemys albipes* (44%).

Adaptations Diurnal and nocturnal.

Foraging and Food Morphological studies show that the gastrointestinal tract is intermediate in structure between that of *Aethomys* and *Mastomys*, suggesting that the diet is mainly vegetable material. In this respect, this species (and *L. brevicaudus*) differs from most other species of *Lophuromys*, which are insectivorous (*L. Lavrenchenko* unpubl.).

Social and Reproductive Behaviour Peaceful and unaggressive. In captivity, neither ♂♂ nor ♀♀ demonstrated any elements of agonistic behaviour towards conspecifics or parapatric *L. brevicaudus*.

Reproduction and Population Structure Females collected in the Beletta Forest during the late dry season and the beginning of the wet season (Apr and May) were pregnant. Embryo number: 2.00 (n = 6 pregnant ♀♀). Sex ratio close to unity.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concerned.

Destruction of montane forests will reduce the geographic range and population numbers of this forest rodent.

Lophuromys cinereus GREY BRUSH-FURRED RAT

Fr. Souris hérissé gris; Ger. Graue Bürstenhaarmaus

Lophuromys cinereus Dieterlen & Gelmroth, 1974. Z. Säugetierk. 39: 338. Marais Mukaba, Parc National de Kahuzi-Biega, E DR Congo.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. Closely related to *L. flavopunctatus*. The status of this species is questionable (Dieterlen 1987) and it is not impossible that it is a grey-coloured mutant of *L. flavopunctatus*. Musser & Carleton (2005) considered *cinereus* to be a synonym of *L. aquilus*, a species treated here as a juvenile synonym of *L. flavopunctatus*. Synonyms: none. Chromosome number: not known.

Description Medium-sized grey unspeckled rat, with relatively short tail. Dorsal pelage harsh, generally brownish-grey; hairs grey at base, brownish-yellow distally, with blackish tip. Ventral pelage pale grey or soft brownish-grey. Large whitish spot on chest in some individuals. Naked parts of fore- and hindfeet blackish-grey. Tail short (ca. 57% of HB), darkly pigmented, short bristles black above, grey below. Skull large, similar to large individual of *L. flavopunctatus*. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species Within the *flavopunctatus* species-group (see Table 20) and likely to be syntopic:

L. flavopunctatus. Pelage speckled; dorsal pelage reddish-brown; ventral pelage pale brown or cinnamon; claws dark.

Lophuromys cinereus

L. rahmi. Pelage unspckled; dorsal pelage reddish-brown; ventral pelage reddish-orange; claws pale or brown.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from near Mukaba in Kahuzi-Biega N. P., Kivu Province, E DR Congo (2275–2350 m). The collecting area covered less than 1 km². Probably an example of an Albertine Rift Valley endemic species.

Habitat Montane swamps of *Cyperus latifolius* (2275 m), and relatively dry short grasslands with *Hagenia abyssinica* and *Kotschy africana* trees.

Abundance Very rare; known only from four specimens from the type locality.

Remarks Very little is known about this species. Contents of four stomachs contained >50% arthropods and molluscs, the remainder being unidentified plant material (Dieterlen 1976b). One adult female had six placental scars, and another had one placental scar.

Conservation IUCN Category: Data Deficient.

Inadequate information to assess conservation status. As for other endemic species of the Albertine Rift Valley, limited geographic range and apparently small population numbers are cause for concern.

Fritz Dieterlen

Lophuromys dieterleni DIETERLEN'S BRUSH-FURRED RAT

Fr. Souris hérissée de Dieterlen; Ger. Dieterlens Bürstenhaarmaus

Lophuromys dieterleni Verheyen, Hulselmans, Colyn & Hutterer, 1997. Bull. Inst. Roy. Sci. Nat. Belgique, Biol. 67: 173.
Mount Oku, Bamenda-Banso Highlands, Cameroon. 2100 m.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. Eisentraut (1973) considered this form to be a montane subspecies of *L. sikapusi* because of its unspckled dorsal pelage. Verheyen *et al.* (1997) showed that, on the basis of craniology, it is a separate species, referable to the *flavopunctatus* species-group (which typically have a speckled pelage) and distinguishable from its geographically closest relative *L. eisentrauti*. Synonyms: none. Chromosome number: not known.

Description Unspckled medium-sized rat. Dorsal pelage soft, darkish-brown, similar to *L. sikapusi*; hairs ca. 11–12 mm. Ventral pelage brownish. Fore- and hindfeet pale brownish. Tail relatively short (ca. 61% of HB), dark brown above, paler below. Skull similar to *L. flavopunctatus*, broad in silhouette, rostrum rather short, clear ridge between t6 and t9 on M¹. Nipples: not known.

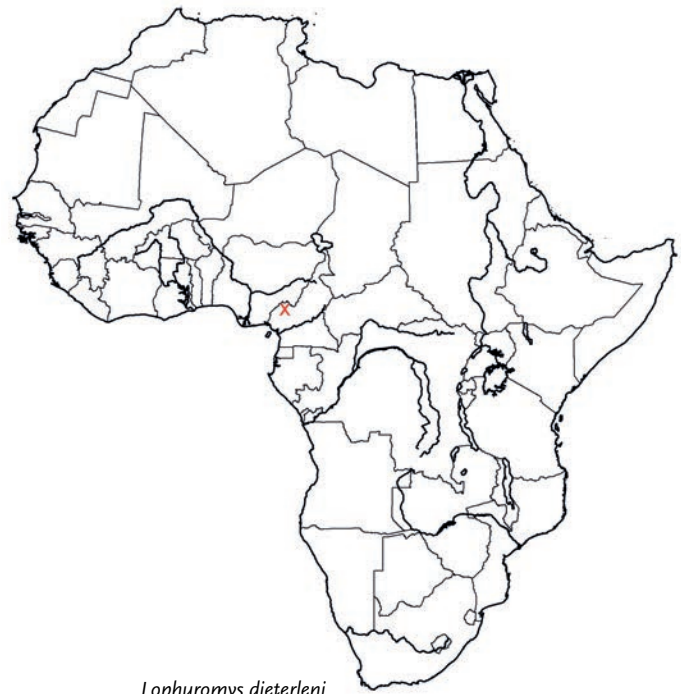

Geographic Variation None recorded.

Similar Species Four other species occur in the Cameroon–Nigeria area and are syntopic, sympatric, or narrowly sympatric:

L. eisentrauti. Pelage speckled; dorsal pelage reddish-brown; ventral pelage pale reddish; probably smaller size. W Cameroon.

L. roseveari. Pelage unspckled; dorsal and ventral pelages reddish-brown, and long; slightly larger on average; claws long and brown. Mt Cameroon.

L. sikapusi. Pelage unspckled; dorsal pelage rufous-rusty to blackish-brown; ventral pelage pale rufous; claws long and dark. Widespread distribution.

Lophuromys dieterleni

L. nudicaudus. Pelage unspckled and harsh; dorsal pelage reddish-brown; ventral pelage pale rufous; claws long and brown; on average smaller size. Central African rainforests.

Distribution Endemic to Africa. Recorded only from the edge of the crater lake on Mt Oku in the Bamenda highlands of Cameroon.

Habitat Montane forests on Mt Oku.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

The very limited geographic distribution, and the decline of forest cover on Mt Oku, suggest that the species should be given Critically Endangered status.

Lophuromys eisentrauti EISENTRAUT'S BRUSH-FURRED RAT

Fr. Souris hérissé de Eisentraut; Ger. Eisentrauts Bürstenhaarmaus

Lophuromys eisentrauti Dieterlen, 1979. Bonner Zoologische Beiträge 29: 296. Mt Lefo, Cameroon.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. A small *Lophuromys* similar to *L. sikapusi* (Dieterlen 1976b). Originally described as a subspecies of *L. sikapusi*, but elevated to a full species by Hutterer *et al.* (1992). Dieterlen (1976b) considered *eisentrauti* to be an 'unspckled' form, although on the basis of skull and molar characters Verheyen *et al.* (1997) placed it in the *flavopunctatus* species-group, i.e. with the 'speckled and short-tailed brush-furred' *Lophuromys*. Its closest relative may be *L. dieterleni*. Synonyms: none. Chromosome number: not known.

Description Smallest species of the genus (together with *L. rahmi* and *L. huttereri*). Pelage soft and unspckled, not very dense; hairs 9–10 mm. Dorsal pelage and flanks reddish-brown, ventral pelage pale reddish (similar to subadult *L. sikapusi*). Fore- and hindfeet reddish-brown. Tail relatively short (ca. 56% of HB), darkish above, paler below. Skull and rostrum short; braincase and interorbital constriction rather broad; zygomatic plate broad, front edge square (not rounded), pointing forward (not downwards). t3 on M² relatively large, t9 on M¹ and M² almost separate. Nipples: not known.

Geographic Variation None recorded.

Similar Species

L. dieterleni. Probably, on average, larger; tail longer; dorsal pelage darker; Mt Oku, Cameroon only.

L. roseveari. Larger; dorsal pelage darker; Mt Cameroon only.

L. sikapusi. Larger, tail longer; dorsal pelage darker; common and widespread.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Mt Lefo (05° 50' N, 10° 20' E), Bafut-Ngamba Reserve, SE of Bamenda, W Cameroon, and probably endemic to the mountain. Map not given.

Habitat Montane cloud forest (at 1800–1900 m; about 700 m below the summit) where lichens, mosses, lycopods and tree ferns are common (Böhme 1975, Eisentraut 1975).

Abundance Very rare; known only by two subadult specimens from the type locality. Uncertain whether *L. eisentrauti* is the only *Lophuromys* on Mt Lefo, or whether it is syntopic with *L. sikapusi*.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Very limited geographic distribution, and the decline of forest cover on Mt Lefo, suggest that the species should be given Critically Endangered status.

Lophuromys flavopunctatus **YELLOW-SPOTTED BRUSH-FURRED RAT (BUFF-SPOTTED BRUSH-FURRED RAT)**

Fr. Souris hérissé à tache jaune; Ger. Gelbgefleckte Bürstenhaarmaus

Lophuromys flavopunctatus, Thomas 1888. Proc. Zool. Soc. Lond. 1888.

Probably obtained at Ankober, Shoa, Ethiopia. (See also Thomas 1903, Proc. Zool. Soc. Lond. 1902: 314.)

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. Previously regarded as a widespread and variable species with several forms or subspecies. The validity of the forms in Ethiopia is complex: two of them, *brevicaudus* and *chrysopus*, are now regarded as distinct species; *brunneus* may also be a valid species, and *simensis* and *zaphiri* are possibly subspecies of *L. flavopunctatus*. Verheyen *et al.* (2002) have revised *L. flavopunctatus* and consider that it can be separated into five species (see profile Genus *Lophuromys*). Synonyms: *aquilus*, *brunneus*, *giaquintoi*, *laticeps*, *majo*, *margarettae*, *rita*, *rubecula*, *simensis*, *zaphiri*, *zena*. Subspecies: none (see also below). Chromosome numbers vary according to locality: $2n = 70$, $FN = 86$ (*laticeps* from E DR Congo and Burundi [Matthey 1967, Dieterlen 1976b, Maddalena *et al.* 1989]); $2n = 68$, $FN = 82$ (*brunneus* from Ethiopia [Lavrenchenko *et al.* 1998b] and *L. flavopunctatus* from Ethiopia [Orlov *et al.* 1989]). Three populations of *laticeps* showed unusually high genetic variation in heterozygosity and polymorphic loci (Verheyen *et al.* 1986).

Description Small reddish-brown rat with thickset body, speckled pelage, short tail, short ears and short hindfeet with long claws. Pelage harsh and brush-like. Dorsal pelage blackish-brownish, brownish-reddish or tawny (depending on locality – see below); hairs reddish with yellow tinge at base, yellowish subterminal band and dark tip. Ventral pelage pale brown tinged with cinnamon; hairs dull brownish at base. In subadults, ventral pelage is more reddish than in adults. Head similar to dorsal pelage; eyes dark and rather small; ears darkly pigmented and naked. Fore- and hindfeet

brown or dark brown; claws long, mostly dark. Tail relatively short (ca. 50% of HB); dark and naked with scattered dark bristles above, dark with whitish bristles below. Nipples: $2 + 1 = 6$ or $1 + 1 = 4$. Considerable variation in size and colouration within populations and throughout geographic range.

Geographic Variation Variation in colour of pelage throughout range. Seven colour morphs previously regarded as subspecies: *margarettae*, *rubecula* and *zena* (Kenya); *aquilus* (Tanzania); *laticeps*, *major*, *rita* (DR Congo). None (except possibly *laticeps* from CE DR Congo, and *simensis* and *zaphiri* from Ethiopia) is now accepted as subspecies.

Similar Species The most widespread sympatric species is *L. sikapusi* (between and eastwards of the Congo and Ubangi rivers):

L. sikapusi. Similar size; pelage soft, unspeckled; dorsal pelage rufous/rusty; tail on average longer and relatively longer (mean 74 mm, 63% of HB); nipples: $1 + 1 = 4$; $2n = 60$ or 62 .

Many other species of *Lophuromys* occur within the geographic range of *L. flavopunctatus*; each has a very restricted range and is sympatric in only a very small area (see maps). In the Congo Basin, potentially sympatric (or syntopic) species are *L. cinereus*, *L. huttheri*, *L. luteogaster*, *L. medicaudatus*, *L. rahmi* and *L. woosmani*; in Ethiopia, potentially syntopic species are *L. melanonyx*, *L. brevicauda* and *L. chrysopus*.

Distribution Endemic to Africa. Rainforest BZ (primarily Eastern Central and South Central Regions), and afroalpine–Afroalpine and Zambezian Woodland BZs at selected places in eastern and central Africa. Widely distributed throughout DR Congo from the Congo Basin (300 m) up to 4500 m in the afroalpine zone of the Rwenzori and the Virunga Mts. Also recorded in W Uganda and S Sudan. Exceptionally may occur in a few areas receiving 800–1000 mm provided there are at least six wet months/year. Distribution patchy on forested mountains and plateaux, mostly above 1000 m where annual rainfall exceeds 1200 mm, in Uganda, Kenya, Tanzania, Malawi, N Zambia, NE Angola and N Mozambique. In Ethiopia, recorded on the plateaux on both sides of the Rift Valley.

Habitat Moist vegetation in a wide range of habitats and altitudes from lowland rainforest and forest tangles to montane grasslands and swamps (Misonne 1963, Delany & Neal 1966, Dieterlen 1976b, Happold & Happold 1989a, b). In drier areas, confined to habitats of permanent moisture such as montane and riverine forests and their adjacent belts of bush, grass and swamp (e.g. around L. Rukwa [Tanzania], in Ngorongoro crater and in the Rift Valley of Kenya).

Abundance A common species in suitable habitats, and often the most numerous species of small rodent in some communities. In

*Lophuromys flavopunctatus*

the highlands of Kivu, DR Congo (where sometimes there were as many as 16 spp. of small mammals), comprised on average 34% of captured small mammals in elephant-grass, 32% in bush and grassland habitats, 19% in secondary montane forest, 48% in bamboo forest with grassy cover, 44% in montane swamps and 53% in afroalpine heath (Dieterlen 1967c, 1976b). Similar levels of abundance have also been recorded in other regions, e.g. E DR Congo, Uganda, Malawi and Ethiopia (Misonne 1963, Hanney 1964, Delany 1971, 1972, Rupp 1980, Yalden 1988, Happold & Happold 1989c, Dudu 1991, Clausnitzer & Kityo 2001). In DR Congo, population densities vary according to habitat, ranging from 9.8 animals/ha in savanna to 19.6/ha in a dry seasonal swamp (Misonne 1963). Home-range in a montane grassland/tangle/forest habitat in Malawi was 3161 m² (1800–4500 m²) (Happold & Happold 1989c).

Adaptations Terrestrial, occasionally up to 1 m above ground. Locomotion by walking, running and scrambling over logs. When frightened or hunted by predators, the escape reaction is to hide rapidly in soil and under rotten vegetation. A ‘high jump’ is possible when an individual is frightened. In favoured habitats (moist soil, dense tangled vegetation), individuals develop a complex network of surface runways (Hanney 1964). Activity occurs during the day and night, but diurnal activity predominates when conditions are suitable. Individuals have a curious odour, quite unlike that of other mice (Woosnam in Thomas & Wroughton 1910). This strong odour, similar to that of shrews, appears to provide protection from predation by some terrestrial carnivores, but not from predatory birds (Dieterlen 1976b, Sillero-Zubiri *et al.* 1995a, Muhmenthaler 1999). The selective value of this character is obvious, but whether there is a relationship between the unattractive odour and the high numerical occurrence of individuals (and how this may effect the populations of other small mammals) is uncertain. Able to live in a very wide range of habitats and climates – and may be one of the most adaptable of small African murid rodents.

Foraging and Food Omnivorous. Foraging for arthropods and other foods occurs in the surface litter and in the upper layer of the soil. The long foreclaws are used for searching and scraping in litter, soil and rotting logs. Food intake is rapid. Individuals in captivity consume on average 3–4 g/day, and a near full-term pregnant female consumed 12 g/day (Delany 1971). In Malawi, the diet (based on percentage of stomachs in which any particular item of food was found) was 81% insects (beetles, larvae, ants, etc.), 39% earthworms, 11% seeds and 8% vertebrate remains (n = 117; Hanney 1964). In E DR Congo, most stomachs contained an equal amount of animal

food (insects, larvae, earthworms, snails) and vegetable food (seeds grains, tubers, but not green matter) (n = 50; Rahm 1972, Dieterlen 1976b). On Mt Elgon, Uganda (>3800 m, near summit), diet is snails, worms and Tipulidae larvae (V. Clausnitzer unpubl.). It appears that this species takes less animal food than most other species of the genus (Dieterlen 1976b) and that the respective portions of animal and plant foods depend on environment and season.

Social and Reproductive Behaviour Little information available. Many individuals in the wild have torn ears and mutilated tails suggesting agonistic behaviour. In captivity, individuals (especially ♂♂) fight and injure each other and deaths (with or without physical damage) are not uncommon. In captivity, individuals are very shy, hiding themselves in vegetation and nesting materials. They are able to utter a feeble cry (Hanney 1964; Delany 1972; Dieterlen 1976b; Muhmenthaler 1999).

Reproduction and Population Structure In most studies, reproduction occurs during the wet season. In Malawi, pregnancies were recorded during the late dry season, throughout the wet season, and at the beginning of the dry season (Oct–May), with the highest pregnancy rates in Nov–Mar (Hanney 1964; Happold & Happold 1989c). In Uganda, two peaks of pregnancy (Sep–Nov and Mar–Jun) coincided with the double peak of annual rainfall (Delany 1971, 1972). In Kivu, DR Congo, three populations living in different habitats and different rainfall regimes showed different patterns of reproductive activity (Table 21).

Reproduction shows considerable flexibility; shorter periods of reproduction are characterized by a lower pregnancy rate and larger litters, and longer periods of reproduction by a higher pregnancy rate and smaller litters. In Uganda, most pregnant ♀♀ are primiparous although a small number of older ♀♀ may be pregnant with their second to fifth litters (Delany 1971). In Uganda, some ♂♂ are fecund at all times of the year, with a higher fecundity rate when monthly rainfall is at its highest (Delany 1971). In Malawi, testis size in adult ♂♂ fluctuates during the year, being smallest in the dry season (when perhaps ♂♂ are not fecund) and largest in the wet season when the fecundity rate is also at its highest (Hanney 1964).

Litter-size varies depending on the environment (see above) and also on the size of the ♀. In Uganda, mean litter-size is 1.9 for ♀♀ of less than 40 g, 2.2 for ♀♀ of 40–49 g, and 2.3 for ♀♀ over 50 g (Delany 1971). In Malawi, litter-size is 2.4 (2–5); 51% of ♀♀ had 3 embryos and 25% had 2 embryos (total n = 43, Hanney 1964). Gestation: 30–31 days. At birth young are naked, with eyes and ears closed, but are rather large (6.5–9.5 g). Growth is rapid: thin

Table 21. Patterns of reproductive activity in populations of *Lophuromys flavopunctatus* living in different habitats with different rainfall regimes.

| Habitat and altitude | Rainfall (months) | Number of months of pregnancies | Pregnancy rate ^a | Litter-size mean (range) |
|-------------------------------|-------------------------|---------------------------------|-----------------------------|--------------------------|
| Cultivations, 1650–1850 m | 9 | 9 | 42% | 2.18 (1–4) |
| Montane forest, 2000–2300 m | 10 | 10 | 57% | 1.99 (1–4) |
| Lowland rainforest, 800–900 m | 9 (but mostly all year) | 12 | 87% | 1.83 (1–2) |

^aPregnancy rate = % of adult ♀♀ (40 g or more) which were pregnant, only during months when pregnancies recorded.

covering of dorsal hair by Day 3, and well covered with hairs by Day 3–6. Eyes open by Day 4–7. Walking by Day 5, and looking like a small adult by Day 9. Adult pelage by Day 30–35. Sexually mature by Day 50–70 when HB: 110–120 mm and weight ca. 45 g (Hanney 1964, Delany 1971, 1975, Dieterlen 1976b).

Sex ratio is fairly constant but varies according to time of year and locality. In Kivu, DR Congo, ♂♂ formed 53.5% of the population at the beginning of the breeding season. In different localities, ♂♂ comprised 51.0% to 55.9% of the population (Dieterlen 1976b, 1985a).

Young are born during many months of the year, and hence populations include young, subadults and adults (of various ages) in most months of the year. In Uganda (two wet seasons and two main periods of pregnancy), each of six age-classes are represented in each month with a tendency for larger numbers of younger animals in Oct–Jan and Apr–Jun (Delany 1971). In Malawi (one wet season and one period of pregnancy), the largest number of young (WT less than 40 g) occurs during and immediately after the wet season (Jan–Jun). These young are responsible for population numbers being at their highest at the time. Mortality of older individuals cause population numbers to be at their lowest in the late dry season (Sep–Dec) (Happold & Happold 1989c).

The large number of ♀♀ that have only one litter (compared with the small number that have two or more litters) suggests that there is high mortality and rapid turnover of the population (Delany 1971).

Predators, Parasites and Diseases The strong odour of this species makes them unattractive and unpalatable for some carnivores (see above). However, they are preyed upon by several diurnal and nocturnal birds such as eagles, herons (Misonne 1963) and Barn Owls *Tyto alba* (Rahm 1960b). Remains of *L. flavopunctatus* were not found in the pellets of African Grass-owls *Tyto capensis* in montane grasslands in Malawi, even though the species was common (Happold & Happold

1986). They are eaten by snakes of the genera *Naja*, *Dendroaspis* and *Bitis* (Allen & Loveridge 1942). Hanney (1964) reported that about 9% of individuals were diseased in Malawi; the percentage fluctuated throughout the year, being lowest during the cold dry season (3–7%) and highest (up to 15%) during the wet season. The most prevalent endoparasites were diphylobothriid larvae (Cestoda), which infested about 6% of individuals. Ectoparasites include five species of fleas (*Ctenophthalmus eximius*, *C. nyikensis*, *C. calceatus*, *Dinopsyllus* sp. and *Xiphiopsylla hyparetis*) (Hanney 1964).

Conservation IUCN Category: Least Concern.

This common and widely distributed species is not threatened at present, although clearance of suitable habitats will reduce numbers and limit the geographic range.

Lophuromys huttereri HUTTERER'S BRUSH-FURRED RAT

Fr. Souris hérissé de Hutterer; Ger. Hutterers Bürstenhaarmaus

Lophuromys huttereri Verheyen, Colyn & Hulselmans 1996. Bull. Inst. Roy. Sci. Nat. Belgique, Biol. 66: 255.

Yaenoro, DR Congo (00° 12' N, 24° 47' E).

Taxonomy Subgenus *Lophuromys*. Species-group: *sikapusi*. An 'unspeckled' short-tailed *Lophuromys*, more closely related to *L. nudicaudus* than to the other representatives of the *sikapusi* species-group (W. Verheyen *et al.* 1996). The characteristics that distinguish this species from other *Lophuromys* are based mainly on the skull and teeth. Synonyms: none. Chromosome numbers: not known.

Description Similar in external characters to *L. nudicaudus*. Compared to *L. nudicaudus*, the skull has a wider and higher rostrum, the zygomatic plate is situated more anteriorly, and t3 on M² is nearly always totally absent. Can only be distinguished unambiguously from *L. nudicaudus* by discriminate analysis (see W. Verheyen *et al.* 1996).

Geographic Variation None recorded.

Similar Species

L. nudicaudus. Probably similar in size; rostrum narrower and lower; zygomatic plate narrow.

L. sikapusi. Zygomatic plate comparatively broad (mean 2.82 mm).

Distribution Endemic to Africa, Rainforest BZ (South Central Region). Recorded from between the Lualaba and Lomani rivers close to junction with the Congo R. (the type locality), and west of the Lomani R. to Ndele (00° 51' N, 21° 05' E); all localities on the left side of the Congo R. (cf. *L. nudicaudus*). The single specimen from Ndele seems to be closer to typical *L. nudicaudus* than to *L. huttereri*.

Habitat Rainforest.

Abundance Rare; known only from about three localities.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

A rare and little-known species.

Lophuromys huttereri

Lophuromys luteogaster BUFF-BELLIED BRUSH-FURRED RAT (HATT'S BRUSH-FURRED RAT)

Fr. Souris hérissée à ventre fauve; Ger. Gelbbauch Bürstenhaarmaus

Lophuromys luteogaster Hatt, 1934. Amer. Mus. Novitat. 708: 4. Medje, Ituri district, DR Congo.

Taxonomy Subgenus *Kivumys*. Species-group: *woosnami*. Synonyms: none. Chromosome number: not known.

Description Small unspeckled olive-brown rat with long tail, similar to *L. woosnami*. Pelage rather harsh. Dorsal pelage uniformly olive-brown and unspeckled, hairs reddish or yellowish at base. Ventral pelage pinkish-cinnamon to buff, hairs unicoloured. Dorsal colour merges to ventral colour on flanks. Head similar colour to dorsal pelage. Ears darkly pigmented with short greyish bristles. Forelimbs yellowish to reddish, hindlimbs pinkish-cinnamon, claws short, relatively weak, pale. Tail relatively long (ca. 100% of HB), dark above, pale below, except darkish tip. (The colour of dry skins in museums fades and loses its brightness when exposed to light). Skull: relatively long; M¹ relatively broad. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

L. woosnami. Similar colour; mostly larger in all body measurements; montane habitats of E DR Congo.

L. flavopunctatus. Dorsal pelage reddish-brown; on average larger HB and skull; tail shorter and relatively shorter; sympatric.

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Recorded from only four localities in rainforest in NE and E DR Congo.

Lophuromys luteogaster

Habitat Lowland rainforests from 700 to 1100 m where dominant trees are either *Gilbertiodendron dewevrei* or *Julbernardia* and *Cynometra* (Hatt 1934, Dieterlen 1975, 1976b, Schlitter & Robbins 1977, Verschuren *et al.* 1983). Also occasionally in sub-montane forests of *Julbernardia* at about 1400 m (F. Dieterlen unpubl.). Of 26 records from

lowland rainforest, 11 were from primary forest, 14 from secondary forest and one from a cultivated area (Dieterlen 1975, 1976b).

Abundance Rare, comprising ca. 0.85% of terrestrial small mammals captured in the region of Irangi (DR Congo). Despite regular collecting during several years, almost 90% of captures ($n = 34$) were during the last three months of dry season and first three months of the wet season (Jun–Nov).

Remarks Terrestrial. Daily activity pattern not well known; mostly captured at night. Mostly insectivorous. Stomach analysis ($n = 9$) shows that the diet is mainly (90–100%) small grubs, caterpillars, small snails, small beetles and termites. Pregnancies recorded in Jun–Nov (no data at other times of year). During these months, pregnancy rate was high (11 out of 14). Embryo numbers: 2 ($n = 11$). Sex ratio 12 ♂♂ : 21 ♀♀. Sexually active ♂♂ had testes length of at least 6 mm.

Conservation IUCN Category: Least Concern.

Although a rare species, it is unlikely to be endangered because it lives in several habitats within the extensive rainforest.

Fritz Dieterlen

Lophuromys medicaudatus MEDIUM-TAILED BRUSH-FURRED RAT (WESTERN RIFT BRUSH-FURRED RAT)

Fr. Souris hérissé a queue moyenne; Ger. Mittelschwänzige Bürstenhaarmaus

Lophuromys medicaudatus Dieterlen, 1975. Bonn. Zool. Beitr. 26: 295. Nyabutera near Lemera, Kivu, DR Congo.

Taxonomy Subgenus *Kivumys*. Species-group: *woosnami*. The only species of *Lophuromys* with a tail of 85% of HB. Closely related to *L. woosnami* and *L. luteogaster*. Synonyms: none. Chromosome number: not known. (Specimens named as *L. luteogaster* collected in the mountains west of L. Kivu by U. Rahm [Verheyen (1964c)], and one specimen from Nyungwe Forest, Rwanda [Elbl *et al.* 1966] are, in fact, *L. medicaudatus* [see Dieterlen 1975]).

Description Small beautiful rat with brightly coloured unspeckled pelage and medium tail length. Dorsal pelage and head uniform dark olive-brown, rather harsh; dorsal hairs paler at base, olive-brown at tip. Ventral pelage dark orange tinged with olive, colouration most intense on the chest; ventral hairs paler at base, olive at tip. Ears darkly pigmented, sparsely haired. Fore- and hindlimbs olive-brown. Tail long (ca. 85% of HB), darkish above, paler below. (The colour of dry skins in museums fades and loses its brightness when exposed to light.) Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

L. woosnami. Larger, ventral pelage pale brown; tail longer (mean 123 mm, 105% of HB); sympatric and syntopic.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of the Albertine Rift Valley of E DR Congo and Rwanda around L. Kivu, at 1850–2500 m (Verheyen 1964c, Dieterlen 1975, 1976b, 1987, Verschuren *et al.* 1983). Specimens named as *L. luteogaster* collected in the mountains west of L. Kivu by U. Rahm (Verheyen 1964c), and one specimen from Nyungwe Forest, Rwanda (Elbl *et al.* 1966) are, in fact, *L. medicaudatus* (see Dieterlen 1975).

Lophuromys medicaudatus

Habitat Montane swamps of *Cyperus latifolius* and montane forests; syntopic with *L. flavopunctatus* and *L. woosnami*.

Abundance Rare; comprised 2.3% (9 specimens) of small mammals in montane swamps and 0.6% (17 specimens) in montane forests (Dieterlen 1975, 1976b).

Adaptations Terrestrial. There appear to be no special adaptations for locomotion in flooded swamp vegetation, but it is assumed that the ability to swim and climb must be essential for survival.

Foraging and Food Omnivorous. Stomach contents ($n = 11$) contained remains of many arthropods and some molluscs (70%, range 30–100%) as well as seeds and fruits.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Mean embryo numbers: 1.6 (range 1–2, mode 2, $n = 5$ ♀♀). Pregnant ♀♀ recorded in Feb, Apr and Jul. Testes length in mature ♂♂: 6–8 mm. Sex ratio 2 : 1 ($n = 30$).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Vulnerable.

This species is threatened because of its rarity and very restricted geographic range; in this respect it is similar to the other Albertine Rift endemics, e.g. *L. rahmi*, *L. woosnami* and *L. cinereus*.

Lophuromys melanonyx BLACK-CLAWED BRUSH-FURRED RAT

Fr. Souris hérissé d’Ethiopie; Ger. Schwarzkralen-Bürstenhaarmaus

Lophuromys melanonyx Petter, 1972. Mammalia 36: 177. Dinshu, Bale, Ethiopia.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*. One of three Ethiopian endemic species of *Lophuromys*. A distinctive species, larger than any other species of *Lophuromys*. Synonyms: none. Chromosome number: $2n = 60$ (Corti *et al.* 1995, Lavrenchenko *et al.* 1997).

Description Medium-sized to large speckled grey-brown rat with large ears; the largest species of *Lophuromys*. Dorsal pelage grey-brown, finely speckled with cream spots. Ventral pelage creamy-white. (Lacks the overall reddish-brown colouration of most of its congeners.) Ears prominent, grey, lightly furred with distinctive tuft of orange or cream at the base of ears. Feet whitish, with a grey wash dorsally, claws distinctively long and black. Tail short (ca. 43% of HB), dark above, whitish on the sides and below. Skull slightly larger than all congeners, with proportionately narrower interorbital region and strong zygomatic plate. Incisors strongly pro-odont (in contrast to moderately orthodont in all other *Lophuromys*). Skin tough (cf. fragile skin of other *Lophuromys* and *Acomys* spp.). Nipples: probably $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

L. brevicaudus. On average much smaller size, pale claws; chromosome number $2n = 68$.

L. chrysopus and other species of the *flavopunctatus* species-group. Smaller, distinctive reddish colouration; chromosome number $2n = 54$ (*chrysopus*) or 68 (Lavrenchenko *et al.* 1997).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Ethiopia at 3200–4300 m, commonly east of the Rift Valley in Bale, but rarely west of the Rift Valley (only from near

Debra Sina and Addis Ababa). Range perhaps more extensive, but not reported from Simien despite extensive surveys (e.g. by Müller 1977).

Habitat Afroalpine moorland, above the treeline (3500 m), ranging down to lower grasslands where open river valleys penetrate the woodland zones. Shares habitat with *Arvicanthis blicki*, *Tachyoryctes macrocephalus* and *Stenocephalemys albocaudata* and *Otomys typus* (Yalden 1988, Sillero-Zubiri *et al.* 1995a).

Abundance The most numerous of the small mammals trapped in the afroalpine habitat of Ethiopia. Comprised 33% of 3083 small mammals in Bale Mts. Population estimates, from live-trapping, suggested densities in different months of 102–658/ha in the grasslands of the Web Valley at 3450 m, and 118–601/ha at 3800–4050 m on the Sanetti Plateau (Sillero-Zubiri *et al.* 1995a). Biomass estimated, on the basis of actual captures, to be 4.9 kg/ha (annual range 3.9–6.6 kg/ha).

Adaptations Active only during daytime. Individuals emerge from their burrows around 08:00h, and the largest numbers of animals above ground occurs at 10:00–12:00h. Activity declines slowly towards 15:00h and sharply thereafter, and no animals are visible above ground after 18:00h (sunrise 06:00h; sunset 18:30h) (see also below). Trapping results reflect this activity: 07:00–12:30h (76%), 12:30–18:30h (23%), overnight (0.5%) (Sillero-Zubiri *et al.* 1995a). The long claws on the forefeet and pro-odont incisors are presumed to be adaptations for burrowing. Large size, relatively short tail and daytime activity might be adaptations to the cold at high altitudes.

Foraging and Food Limited data from stomach analysis suggest that the diet is primarily leaves of dicotyledonous herbs (93% occurrence), with smaller amounts of monocotyledonous leaf (2%), seeds (3%) and insects (2%) (Yalden & Lagen 1992). This diet differs from that of most other *Lophuromys*, which are largely insectivorous (Dieterlen 1976b), and from sympatric *Arvicanthis blicki*, which eats much monocotyledonous leaf (30%) as well as herbs.

Social and Reproductive Behaviour Lives in mixed colonies with *Arvicanthis blicki*; both species are diurnal, live in burrows and utter high-pitched alarm squeaks that warn of intruding predators (including humans). Because of the difficulty of distinguishing this species from *Arvicanthis blicki* in the field, observations (given above) refer to the mixed colonies.

Reproduction and Population Structure Pregnant and lactating ♀♀ found throughout the year. The occurrence of pregnancy is 80–100% at beginning of short wet season in Apr, falls to 40% in May (rainfall lower and variable), rises to 80–100% at the

beginning of the main wet season (Jun–Jul), declines to 40% in the wet season (Aug–Oct), and reaches its lowest level of ca. 20% during dry season (Nov–Mar). This pattern suggests at least two litters per year. Young mainly enter the trappable population in Oct–Feb, contributing ca. 15% of captures; apparent slowness of recruitment is puzzling; possibly due to slow growth or effects of high population density. Mean embryo number: 1.88 ± 0.38 ($n = 52$ pregnancies; Sillero-Zubiri *et al.* 1995a). Sex ratio close to unity.

Predators, Parasites and Diseases Important prey of Ethiopian Wolves in Bale, comprising 40% of 1307 prey occurrences in 689 scats and 15% by volume of prey (Sillero-Zubiri & Gottelli 1995); the third commonest prey after *Tachyoryctes macrocephalus* and *Arvicanthis blicki*. Probably also prey of diurnal raptors, but no detailed information available.

Conservation IUCN Category: Vulnerable.

Although abundant in suitable habitats, geographic range is very limited. Schlitter (1989) suggested it should be listed as rare.

Lophuromys nudicaudus FIRE-BELLIED BRUSH-FURRED RAT

Fr: Souris hérissé à ventre feu; Ger: Rotbauchige Bürstenhaarmaus

Lophuromys nudicaudus Heller, 1911. Smithson. Misc. Coll. 56 (17): 11. Efulen, Bula country, Cameroon.

Taxonomy Subgenus *Lophuromys*. Species-group: *sikapusi*. Closely related to *L. sikapusi* and *L. huttereri* (see W. Verheyen *et al.* 1996 for a review). Previously considered to be a subspecies of *L. sikapusi*, but now considered to be a valid species on the basis of skull and tooth characters (Rosevear 1969; Dieterlen 1976b, 1979a). The specific name (*nudicaudus* = naked tail) is misleading (Rosevear 1969). Synonyms: *afar*, *naso*, *nudicaudatus*, *parvulus*, *tullbergi*. Subspecies: two. Chromosome number: $2n = 56$, with considerable polymorphism (Verheyen & Van der Straeten 1980).

Description Small unspeckled species with harsh pelage, relatively short tail and relatively short hindfeet. Dorsal pelage dark

brown with reddish tinge, stiff and harsh; hairs paler at base. Ventral pelage bright rufous (especially in young animals) or yellowish-red. Overall colouration resembles that of young *L. sikapusi*. Head similar to dorsal pelage, throat and chest similar to ventral pelage. Fore- and hindlimbs brownish; claws long, usually pale or brown. Tail short (ca. 58% of HB) with black bristles, dark above, paler below. Skull: rostrum narrow; zygomatic plate narrow. Nipples: $2 + 1 = 6$ (W. Verheyen *et al.* 1996).

Geographic Variation The two subspecies are distinguished only by craniometric analysis (W. Verheyen *et al.* 1996).

L. n. nudicaudus: north and west of Congo R. to Sanaga R.
L. n. tullbergi: between Cross and Sanaga rivers, and on Bioko I.

Similar Species

L. sikapusi. Larger (HB: 136 (122–153) mm); sympatric.
L. huttermi. Probably similar in size and characters; rostrum wider and higher; zygomatic plate wide.

Distribution Endemic to Africa. Rainforest BZ (West Central Region), north and west of Congo and Ubangi rivers and westwards almost to Cross R. in Nigeria. Recorded from Congo, SW Central African Republic, Gabon, Equatorial Guinea (Rio Muni and Bioko I.), Cameroon and E Nigeria. Recorded also at one locality on the right bank of Aruwimi R. (DR Congo), and may extend westwards along Congo R. to its junction with Ubangi R.

Habitat Gaps and clearings within the rainforest and along logging roads (Rosevear 1969; Ray 1996; Malcolm & Ray 2000). Recorded from grassy and open habitats on the forest edge on Mt Cameroon (100–600 m) and Bioko I. (450–1200 m) (Eisentraut 1973). Does not occur in closed canopy rainforests.

Abundance Relatively rare, especially in disturbed forests. In SW Central African Republic, comprised 2.4% of small mammals (n = 704) along secondary logging roads (Ray 1996).

Remarks Terrestrial and diurnal (Rosevear 1969, Malcolm & Ray 2000). Stomach contents of two individuals consisted mainly of insects (80–100%) (Dieterlen 1976b). Solitary (Rosevear 1969). Number of embryos: 2, 5 (n = 2).

Conservation IUCN Category: Least Concern.
 Probably not threatened because of its large geographic range.

Lophuromys rahmi RAHM'S BRUSH-FURRED RAT

Fr. Souris hérissé de Rahm; Ger. Rahms Bürstenhaarmaus

Lophuromys rahmi Verheyen, 1964. Rev. Zool. Bot. Afr. 69: 206. Bogamanda near Lemera, Kivu, DR Congo.

Taxonomy Subgenus *Lophuromys*. Species-group: *flavopunctatus*.
 Synonyms: none. Chromosome number: not known.

Description Small beautiful dark reddish unspeckled rat with short-tail, very short hindfeet and short rounded ears. Pelage rather harsh. Dorsal pelage dark reddish-brown, dorsal hairs pale reddish usually with dark tip. Some individuals may have pale tips to dorsal hairs to give slight speckling to pelage. Flanks paler than dorsal pelage. Ventral pelage bright reddish-orange in both young and adults; hairs paler at base. Head similar to dorsal pelage but duller. Ears short and rounded. Hindfeet very short. Tail short (ca. 51% of HB), darkish-brown above, paler below. Skull: short with rather broad interorbital constriction. Nipples: not known.

Geographic Variation None recorded.

Similar Species

L. cinereus. On average larger; dorsal pelage greyish-brown; very rare.
L. flavopunctatus. On average larger; dorsal pelage reddish-brown; widespread and common.
L. medicaudatus. Similar in size; tail relatively longer; pelage olive-brown; limited distribution, rare.
L. woosnami. On average larger; tail longer and relatively longer; dorsal pelage brown tinged with olive-grey; limited distribution, rare.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Restricted to montane forests bordering Albertine Rift Valley of E

*Lophuromys rahmi*

DR Congo and Rwanda around L. Kivu at 1900–2500 m (Dieterlen 1976b, 1987, Verschuren *et al.* 1983). Also Bwindi Forest, SW Uganda (Kasangaki *et al.* 2003).

Habitat Dense primary montane forest especially in *Albizia gummifera*–*Carapa grandiflora*–*Parinari excelsa* forest. Also recorded in secondary forest with *Hagenia* and *Macaranga* trees, and in sparse bamboo stands (*Hagenia abyssinica*–*Sinarundinaria alpina*) with ground cover of grass (Dieterlen 1976b). May show a preference for habitats with small streams (Rahm 1967) although this preference is uncertain (Dieterlen 1976b, Verschuren *et al.* 1983).

Abundance Extremely rare, comprising less than 0.05% of terrestrial small mammals captured in montane forests and grasslands.

Remarks Terrestrial. Probably burrows amongst roots of trees. Mostly active during the night (Rahm 1967). Omnivorous, preferring insects (mostly larvae), small grubs, caterpillars, beetles, ants, etc. May also eat seeds. Forages on ground in leaf litter (Dieterlen 1976b). Embryo numbers: 2 ($n = 2$). Pregnant ♀♀ recorded in Feb and Jul. Adult size attained when HB >95 mm and weight >30 g. Males fecund when testes 5–10 mm. Sex ratio 16♂♂ : 5♀♀ (Dieterlen 1976b).

Conservation IUCN Category: Endangered.

This species is threatened because of its rarity and very restricted geographic range; in this respect it is similar to the other Albertine Rift endemics – *L. medicaudatus*, *L. woosnami* and *L. cinereus*. Schlitter (1989) classified the species as rare.

Lophuromys roseveari ROSEVEAR'S BRUSH-FURRED RAT (MOUNT CAMEROON BRUSH-FURRED RAT)

Fr. Souris hérissé de Rosevear; Ger. Rosevears Bürstenhaarmaus

Lophuromys roseveari Verheyen, Hulselmans, Colyn and Hutterer, 1997.

Bull. Inst. Roy. Sci. Nat. Belgique, Biol. 67: 167. Musake (slopes of Mount Cameroon), Cameroon. 1850–2200 m.

Taxonomy Subgenus *Lophuromys*. Species-group: *sikapusi*. Previously considered to be a montane race of *L. sikapusi* (Eisentraut 1963, 1973, Rosevear 1969, Dieterlen 1976b, 1979a) and now considered as a valid species (Verheyen *et al.* 1997). Morphologically and morphometrically similar to other species in the *sikapusi* species-group, but its status and systematic relationships need investigation (Verheyen *et al.* 1997, Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Medium-sized reddish-brown unspeckled rat, with long dorsal hairs on rump and a short tail. Dorsal pelage reddish-brown; hairs reddish at base with reddish-brown tip. Hairs on rump long and dense (13–14 mm). Ventral pelage pale reddish-brown or dark cinnamon-brown. Head similar to dorsal pelage. Ears rather large.

Fore- and hindlimbs brown; claws very long, variable and brownish. Tail short (ca. 50% of HB), dark brown. Skull (compared to *L. sikapusi*): slender and fragile, with narrow choanae, more inclined borders of the zygomatic plates, supraorbital ridges and notch weakly developed, and zygomatic arches more slender; mandible relatively longer and with a more slender angular process (Verheyen *et al.* 1977). Nipples: 2 + 1 = 6, 1 + 1 = 4.

Geographic Variation None recorded.

Similar Species

L. sikapusi. Similar in size; ears on average shorter; dorsal pelage reddish-brown (probably paler); different skull characters (details in profile); widespread and common.

Lophuromys roseveari

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Mt Cameroon only. All specimens ($n = 44$) were collected from several localities on the slopes of Mt Cameroon at 1200–3000 m (Eisentraut 1963, 1973).

Habitat Montane forest, grasslands, forest fringes, small patches of woodland, gardens and plantations.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Distribution is restricted; changes in land use on the mountain may be cause of concern.

Lophuromys sikapusi RUSTY-BELLIED BRUSH-FURRED RAT

Fr. Souris hérissé de l'Ouest; Ger. Braunbauchige Bürstenhaarmaus

Lophuromys sikapusi (Temminck, 1853). Esquisses Zoologiques sur la côte de Guinée, p. 160. Dabocrom, Ghana.

Taxonomy Originally described in the genus *Mus*. Subgenus *Lophuromys*. Species-group: *sikapusi*. One form (*eisentrauti*) previously considered to be a synonym by Musser & Carleton (1993) now considered to be a valid species. Musser & Carleton (2005), following Verheyen *et al.* (2000), regard *ansorgei* (SW DR Congo near the mouth of the Congo R., Uganda, W Kenya, N Tanzania) and *angolensis* (SW DR Congo near the mouth of the Congo R. and NW Angola) as valid species; here they are retained within *L. sikapusi* pending further revision. Synonyms: *afer*, *ansorgei*, *angolensis*, *mantufeli*, *pyrrhus*, *tullbergi*. Subspecies: none. Chromosome number: $2n = 60$, FN = 66–70 (Côte d'Ivoire; Matthey 1958); $2n = 64$, FN = 76 (Mt Nimba, Guinea; Gautun *et al.* 1986).

Description Small unspeckled short-tailed rat. Pelage comparatively soft and less stiff than in other *Lophuromys*. Dorsal pelage rufous to rusty; blackish-brown in some populations. Ventral pelage pale rufous (most) or bright red (Côte d'Ivoire). Head pointed; eyes small, ears short. Limbs short. Fore- and hindfeet short, reddish-brown, with long dark curved claws. Digit 1 of forefoot much reduced. Tail short (ca. 64% of HB), dark with scaly rings and short dark bristles. Skull: zygomatic plate comparatively broad (2.82 [2.4–3.1 mm]). Nipples: $1 + 2 = 6$.

Geographic Variation Dorsal pelage is darkish-brown, and ventral pelage is also unusually dark, in *ansorgei* from W Kenya. Ventral pelage strikingly bright red in *pyrrhus* from N Uganda and S Sudan (Dieterlen 1987).

Similar Species

L. roseveari. Ear on average longer; dorsal pelage reddish-brown to blackish-brown; different skull characters (details in species profile); Mt Cameroon only, where may be sympatric.

L. flavopunctatus. Pelage harsh and brush-like, speckled; dorsal pelage blackish-brown; ventral pelage pale brown; tail on average shorter and relatively shorter; nipples $2 + 1 = 6$ or $1 + 1 = 4$; $2n = 68$ or 70.

Distribution Endemic to Africa. Rainforest BZ (Western, West Central and East Central Regions) and adjacent Rainforest–Savanna Mosaic. Recorded from Sierra Leone to Cameroon, southwards to Gabon, Equatorial Guinea, Congo, SW DR Congo and N Angola, and east to Central African Republic, N DR Congo (north of Congo R.), S Sudan, Uganda and W Kenya. In Tanzania, patchy distribution in some montane habitats (Dieterlen 1976b).

*Lophuromys sikapusi*

Habitat Dense moist grasslands, secondary growth, agricultural fields, abandoned farmlands, swamps and grassy plantations where there is abundant low cover. In primary and secondary rainforests, occurs only in grass and herbaceous patches (e.g. after a tree fall) and where grass and bushes grow in open areas. These habitats are preferred because they provide moist soil for digging, and abundant insects, throughout the year (see below). At Mt Nimba, Guinea, occurs up to 1600 m (Gautun *et al.* 1986). In Uganda, very common in heavily grassed bush country (Delany & Neal 1966).

Abundance Common and often numerous in preferred moist habitats, e.g. in S Nigeria comprised 46% of small rodents in swampy stream banks ($n = 43$, 7 spp.) and 13% in arable fields ($n = 138$, 8 spp.) (Funmilayo & Akande 1979a). Uncommon in primary rainforest, e.g. 2.9% of seven species of small rodents ($n = 482$) in a Nigerian rainforest, all individuals occurring in open herbaceous patches (Happold 1977). In Uganda, in grassland, comprised 14.5% of rodents ($n = 931$, 10 spp.) (Cheeseman & Delany 1979).

Adaptations Terrestrial, nocturnal and crepuscular (Cheeseman 1977). The long claws are used for scratching and digging soil while making tunnels through litter and long grass (Happold 1987). Nests of dry grass are constructed on or just under the surface. As in other species of the genus, the strong odour may be unattractive, and may reduce predation by some terrestrial carnivores but not by predatory birds (Dieterlen 1976b). Normally lives in moist rank dense habitats that are not burned; however, in grassland in Uganda, numbers declined after burning (Cheeseman & Delany 1979).

Foraging and Food Insectivorous and omnivorous. Forages by searching and digging in dead leaves or litter, where ants, termites, other small or large insects, millipedes, earthworms, molluscs and even carrion are devoured opportunistically. May also eat soft fallen fruits and small seeds of certain tree species. In Central African

Republic, the diet (as assessed by volume) varied according to season: in the dry season 60% insects (especially ants), 18% vegetable pulp and 22% miscellaneous (hairs, soil and myriopods etc.); and in the wet season, 46% insects (mainly ants and termites), 38% vegetable pulp, 5% seeds and 10% miscellaneous (hair, soil, etc.) (Genest-Villard 1980). In Uganda, ants and other insects comprised the major proportion of the food ($n = 37$ stomachs; Delany 1964). In S Nigeria, insects were found in 78% of stomachs, earthworms in 85% and plant material in 20% ($n = 61$ stomachs; Funmilayo & Akande 1979b). Similar diets are reported from DR Congo (Verheyen & Verschuren 1966), Rwanda (Misonne 1965a) and Côte d'Ivoire (Heim de Balsac & Aellen 1965).

Social and Reproductive Behaviour Probably solitary. Torn ears and mutilated tails are not uncommon, suggesting intra-specific aggression.

Reproduction and Population Structure Young ♀♀ become pregnant when 40 g (Happold 1987). In Uganda, a relatively high proportion of pregnant/lactating ♀♀ occurred in the wet seasons (Mar–Jun and Sep–Dec; $n = 183$; Delany & Neal 1969, Cheeseman & Delany 1979). In S Nigeria, pregnancies also recorded mainly in the wet season (Mar–Jun), with reduced pregnancy rates in the 'little dry season' (Jul–Aug) and in the 'long dry season' (Nov–Feb) (Happold 1974). Gestation: about 30 days (Genest-Villard 1968). Litter-size usually 2–3. Mean embryo numbers: 2.6 (range 1–3, $n = 8$) in Virunga Mts, DR Congo (Verschuren *et al.* 1983); 3.0 (range 2–5, $n = 13$) in S Nigeria (Happold 1974). At birth, young are precocial, weight ca. 8 g. Animals born in captivity weighed 35 g at three weeks of age (= 50% adult weight), and adult weight when 5–8 weeks (Genest-Villard 1968).

Predators, Parasites and Diseases In grasslands of Rwenzori N. P., Uganda, various species of predatory birds, carnivores (mongooses, genets, servals) and snakes were potential predators of small rodents (Cheeseman & Delany 1979).

Conservation IUCN Category: Least Concern.

A widely distributed and common species.

Lophuromys woosnami WOOSNAM'S BRUSH-FURRED RAT

Fr. Souris hérissé de Woosnam; Ger. Woosnams Bürstenhaarmaus

Lophuromys woosnami Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 146. Mubuku Valley Rwenzori East, Uganda; 6000 ft (1820 m).

Taxonomy Subgenus *Kivumys*. Species-group: *woosnami*. Synonyms: *prittiei*, undescribed (see below). Subspecies: two or three (Dieterlen 1976b). Chromosome number: $2n = 42$, $FN = 72$ (Dieterlen 1976b, Maddalena *et al.* 1989).

Description Medium-sized and slender-bodied rat with a long tail, long ears, long hindfeet and comparatively short claws. Pelage soft and conspicuously glossy; unspeckled. Dorsal pelage brown tinged with olive-grey; hairs reddish-brown at base. Ventral pelage pale brown tinged with reddish. In subadults, reddish colouration of dorsal and ventral pelage is brighter and more intense than in adults. Ears long, naked, rounded at tip. Fore- and hindfeet whitish with comparatively short claws. Hindfoot long (cf. other species in genus). Tail long (ca. 105% of HB), mostly naked with dark bristles, dark above, pale flesh-colour below. Nipples: $1 + 1 = 4$.

Geographic Variation

L. w. woosnami: Rwenzori Mts. HB: ca. 110 mm.

L. w. prittiei: highlands of Kigesi, Uganda; Virunga Mts in Uganda, Rwanda, DR Congo; Nyungwe Forest in Rwanda and Kibira Forest in Burundi. HB: ca. 115 mm.

L. w. undescr.: west of *L. Kivu*, DR Congo. HB: ca. 121 mm.

Similar Species

L. flavopunctatus. Dorsal pelage reddish-brown; E shorter; HF shorter; T much shorter.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ in Uganda, Burundi, Rwanda and DR Congo. Recorded from the Albertine Rift Valley and bordering mountains from Rwenzori Mts in the north to the Itombwe massif (E DR Congo) and mountains of Burundi in the south. Distribution discontinuous, confined to forested mountains on both sides of the Rift Valley; 1800–3880 m.

Habitat Undergrowth in montane forests, cleared areas in forests, old and new bamboo forests, and amongst rocks in afroalpine vegetation (*Senecio*, *Lobelia*).

Abundance Common in suitable habitats and often the most numerous species of small rodents. Commonly syntopic with *L. flavopunctatus*. In many habitats in Kahuzi-Biega N. P., E DR Congo, one species of *Lophuromys* was considerably commoner than the other suggesting inter-specific competition. Percentage occurrence of *L. woosnami* and *L. flavopunctatus* in small mammal communities was, respectively, 25% and 19% in montane secondary forests, 42% and 6% in cleared montane primary forest, 13% and 4% in undisturbed montane primary forest, 56% and 8% in old bamboo, and 20% and 48% in young bamboo with grassy cover (Dieterlen 1976b).

Adaptations Terrestrial long-footed rat; runs with a 'jumping gallop' and good at climbing. This kind of locomotion, as well as the

*Lophuromys woosnami*

long legs, long tail and long ears suggests that these mice are very mobile and probably have a large home-range. Activity is mostly nocturnal (Rahm 1967, Delany 1972). Captive ♀♀ constructed simple nests of dry grass and leaves.

Foraging and Food Omnivorous. Stomach contents contained 40–50% arthropods (and some molluscs) and 50–60% vegetable material, seeds and bulbs (but not green matter) ($n = 15$; Dieterlen 1976b, Verschuren *et al.* 1983). Captive animals preferred meal worms, grasshoppers and dry insect larvae etc., but also ate sweet apples, peanuts and grains of sunflowers. Drinking water is essential.

Social and Reproductive Behaviour Captive animals are tame from the first day of captivity, showing no fear or panic even when handled for the first time. When in captivity for several months, adults and their young live together peacefully and without aggression towards one another. Individuals exhibit mutual grooming. Olfactory communication seems to be important. The typical odour, caused by sebaceous glands in the glossy pelage, probably has a socially stimulating effect (Dieterlen 1976b). Females exhibit 'midwifery' behaviour when a mother is giving birth; they try to get hold of the umbilical cord and, some moments later, to 'steal' and eat the placenta. Young are raised communally, several ♀♀ participating in the care of the young (Dieterlen 1976b); this behaviour is similar to that of *Acomys* spp. (Dieterlen 1962).

Reproduction and Population Structure In Kivu Province, DR Congo, reproduction is seasonal, occurring during the wet

season (Sep–Apr), with peaks in pregnancy rate (80–100%) in Oct–Dec and in Mar–Apr (Dieterlen 1976b). After a transition period in May, pregnancies not recorded during the dry season (Jun–Aug). Gestation: at least 32 days. At birth, young are precocial; postnatal development is rapid. Mean embryo numbers: 1.94 (1–3; mode 2 [84% of total]; $n = 96$). Females and ♂♂ became sexually active when 7–8 weeks old; at this age ♂♂ weigh 36–40 g (testes 10–12 mm). Adult ♂♂ weighing 50–60 g have permanently large testes of 20–25 mm. Sex ratio: 58% ♂♂: 42% ♀♀ ($n = 454$).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

The forests on the mountains of the Albertine Rift Valley, the only habitat of this species, are fragmented and declining in area. The future of the species depends on adequate protection of these forests.

GENUS *Uranomys*

Rudd's Brush-furred Mouse

Uranomys Dollman, 1909. Ann. Mag. Nat. Hist., ser. 8, 4: 551. Type species: *Uranomys ruddi* Dollman, 1909.

Uranomys ruddi.

A monotypic genus widespread in savannas of West and East Africa. The genus is characterized by small size, dorsal pelage composed of coarse brownish brush-like hairs, white ventral pelage and short tail. The skull has pro-odont incisors (except in one form), the palatine bones extend posteriorly to M³ and partly cover the mesopterygoid fossa, the small cheekteeth are similar to those of *Acomys* spp., and there is an enlarged process on the external aspect of the mandibular ramus (Figure 43). Further details are given in the species profile. The genus originally contained seven species (see synonyms below), but is now considered to contain only one species, *Uranomys ruddi*.

The genus is closely related to *Lophuromys* and *Acomys*, and (like these genera) is placed in the subfamily Deomyinae of the Muridae (Musser & Carleton 2005) rather than in the subfamily Murinae as in previous classifications (e.g. Musser & Carleton 1993). Other investigations (biochemical, molecular and karyological) confirm the monophyletic origin of *Uranomys*, *Lophuromys* and *Acomys*. Full details of these relationships are given in Musser & Carleton (2005, and references therein). The single species is *Uranomys ruddi*.

D. C. D. Happold

Figure 43. Skull and mandible of *Uranomys ruddi* (HC 1748).

Uranomys ruddi RUDD'S BRUSH-FURRED MOUSE

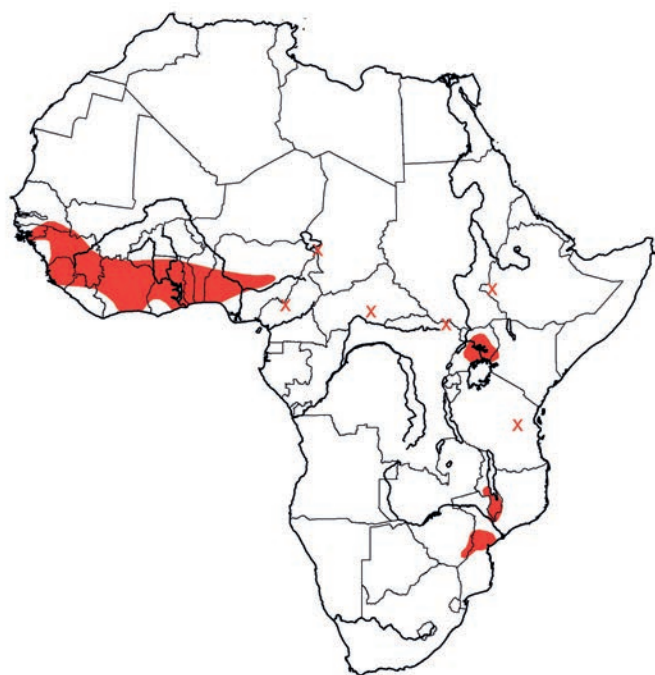

Fr. Souris de Rudd; Ger. Rudds Bürstenfellmaus

Uranomys ruddi Dollman, 1909. Ann. Mag. Nat. Hist., ser. 8, 4: 52. Kirui, Mount Elgon, Kenya. 6000 ft (1820 m).

Taxonomy Now considered as a single species with a very broad distribution (Verheyen 1964a; see also profile Genus *Uranomys*); however, variations in chromosome number perhaps indicate that more than one species is present. Synonyms: *acomyoides*, *foxi*, *oweni*, *shortridgei*, *tenebrosus*, *ugandae*, *woodi*. Subspecies: none. Chromosome number varies geographically: $2n = 50$ (Senegal), $2n = 58$ (Côte d'Ivoire), $2n = 52$ (Central African Republic).

Description Small mouse with small limbs, short tail and stiffened hairs on back and rump. Pelage short and stiff. Dorsal pelage grey to grey-brown, speckled with pale brown and black; hairs dark grey with pale brown tip, or with pale brown terminal band and black tip. Dorsal hairs stiffened as in an artist's brush, and not easily rubbed the wrong way. Dorsal hairs not spiny as in Spiny Mice (*Acomys* spp.). Ventral pelage dirty-white, sometimes tinged with pale cinnamon; colour of flanks merges gradually to colour of ventral pelage. Head rather slim and pointed, with small eyes and small ears. Chin, throat, chest and limbs white. Limbs short. Tail short (ca. 60% of HB), brownish, with scales and numerous very small black bristles. Skin thin and fragile; many individuals have damaged ears, and tail is frequently shortened or completely absent. Incisor teeth pro-odont (although occasionally opisthodont in some juveniles). See also genus profile. Nipples: $3 + 3 = 12$.

Geographic Variation The form *acomyoides* from Ghana has orthodont incisors (Ingoldby 1929 in Musser & Carleton 2005).

Uranomys ruddi

Similar Species

Acomys spp. Dorsal hairs spiny and thicker.

Mus minutoides/musculoides. Smaller, without stiffened hairs.

Distribution Endemic to Africa. Guinea Savanna BZ, Northern Rainforest–Savanna Mosaic, Eastern Rainforest–Savanna Mosaic, and parts of Zambezian Woodland BZ. In West Africa, recorded from Sierra Leone, Gambia, Guinea, Liberia, Côte d'Ivoire, Ghana, Togo, Benin and Nigeria. In central and eastern Africa, recorded in Uganda, Zimbabwe, Mozambique and Malawi. Isolated records in N Cameroon, Central African Republic, Chad, NE DR Congo, C Tanzania and W Ethiopia. May be more widespread than records indicate (see Abundance). Distribution disjunct.

Habitat Grasslands. The rarity of the species in most places, and its abundance in a few localities (see below), suggest that the preferred habitat has abundant grasses, few trees and moist soil, which provides moist or semi-swampy conditions. Also occurs in farmland (where soil is moist and friable) and oil palm plantations (where there are moist grasses and grass litter). One individual in Malawi was found 'in hole of Mole-rat on wooded hills', and others were found close to a river swamp where there were many ant and termite mounds (Hanney 1965).

Abundance Generally a rare species and seldom encountered. Not recorded from many savanna habitats and rare in others. However, is quite common at a few study sites, e.g. comprised 29% of small rodents in grass savanna at Lamto, Côte d'Ivoire ($n = 745$; Bellier 1968), 31% in farmland at Ibadan, Nigeria ($n = 710$; Happold 1974), 44% in grass swamp at Ibadan ($n = 86$; D. C. D. Happold unpubl.) and 55% in grass savanna at Dabou, Côte d'Ivoire ($n = 838$; Bellier 1968). Comprised 8% ($n = 1448$) in oil palm plantation in Côte d'Ivoire (Bellier 1968). Population numbers not adversely affected by burning of grasses at Ibadan, Nigeria, probably because of fossorial habits (D. C. D. Happold unpubl.).

Adaptations Nocturnal and crepuscular; terrestrial. Brush-furred Mice dig burrows, using their short strong feet. An excavated nest (in Côte d'Ivoire) about 15 cm below ground had a nest chamber 6–8 cm in diameter lined with fresh cut grass; another tunnel descending to about 30 cm below ground (Bellier 1968). Entrance holes were plugged. Brush-furred Mice seem to be partly fossorial; specimens in captivity burrowed under litter and grass when disturbed, and they blocked the entrances to their burrows and nestbox with soil which was sometimes glued together with fluid (? saliva) (D. C. D. Happold unpubl.). The pro-odont incisor teeth may be used for catching and holding insect prey, in a similar manner to shrews.

Foraging and Food Primarily insectivorous: the contents of two stomachs contained adult insect remains, dipteran larvae and ant pupae (Malawi; Hanney 1965). Vegetable foods include cassava

(manioc) and bulbs of savanna plants (Bellier 1968). Food has not been found in burrows.

Social and Reproductive Behaviour Little information. Burrows in Côte d'Ivoire were inhabited by two adults (Bellier 1968). In captivity several individuals live together amicably.

Reproduction and Population Structure In Côte d'Ivoire (Bellier 1968), pregnancies recorded in all months except Jan (early dry season) and juveniles in all months except Oct and Feb. Peak of reproductive activity in late wet season (Aug–Dec incl.). Seasonal variation in mean number of embryos: 4.3–5.7 (late wet season), 2.6–3.7 (dry season and early wet season) (Bellier 1968). Minimum weight at pregnancy: 22 g (Happold 1974). Sex ratio (live trapping) was 3 : 1 (Nigeria; D. C. D. Happold unpubl.).

Population structure unknown. At Ibadan, Nigeria, during a 5-month study, 72% of individuals were caught once and 18% were caught twice (n = 39 individuals), suggesting a rapid turnover of the population (D. C. D. Happold unpubl.).

Predators, Parasites and Diseases Preyed upon by Barn Owls *Tyto alba* (Rosevear 1969).

Conservation IUCN Category: Least Concern.

The widespread distribution suggests that the species is not threatened. However, its rarity (in most habitats) and loss of suitable habitat may be cause for concern.

*Formerly *Tatera*

Members of this large subfamily, numbering 16 genera and about 101 species (Musser & Carleton 2005), occur throughout much of Africa and across the Palaearctic desert and steppe, from Asia Minor and the Middle East to southern Mongolia and northern China. In Africa, there are 12 genera and 71 species (see list above). Gerbils mostly live in arid and semi-arid environments, mostly in areas of sparse vegetation. Within Africa, they occur in many biotic zones except the Rainforest and Afroalpine BZs. Typical habitats include sandy and clay deserts, dunes and alluvium with meagre grass or brush cover, gravelly plains and semi-deserts, and a wide mixture of grasslands and woodlands from very dry and open to moderately moist. Certain forms, such as *Pachyuromys* and some *Gerbillus*, thrive in some of Africa's bleakest, seemingly inhospitable, habitats. In such environments, gerbils fill a terrestrial and largely granivorous niche

(the herbivorous *Psammomys* is a notable exception); most species are nocturnal and a few are diurnal (*Psammomys* and some *Meriones*).

Most gerbilline genera (12 of 16) contain species with distributions in Africa, and many are endemic to the continent (*Ammodillus*, *Desmodilliscus*, *Desmodillus*, *Gerbilliscus* [formerly *Tatera*], *Gerbillurus*, *Microdillus*, *Pachyuromys*, *Taterillus*). Three genera have distributions that include Africa and parts of the Middle East or Asia (*Gerbillus* [including *Dipodillus*], *Meriones*, *Psammomys*), and one of these has its greatest number of species within Africa (*Gerbillus* – 39 of 51 spp.). *Meriones* is the only genus that contains more species with ranges outside of the continent (13 of 17); the four species distributed entirely or partially in Africa occur only along the Mediterranean coast. *Psammomys*, too, has a predominantly North African distribution but also reaches to the near Middle East and Arabian Peninsula. Clearly, African environments have figured prominently in the evolutionary diversification of the subfamily, and the continent is considered by some to be its place of origin (e.g. Lay 1972). The present-day concentration of the early-branching clades of the Gerbillinae within the sub-Saharan region (namely Gerbillurina, Taterillina and Ammodillini (Pavlinov *et al.* 1990) is consistent with this biogeographic interpretation.

Most African gerbils are small to medium in body size, but extremes of very small (*Desmodilliscus*, some *Gerbillus*) and large (*Gerbilliscus*, *Psammomys*, some *Meriones*) are also represented. Body form ranges from stout and compact (*Pachyuromys*) to slender and gracile (*Gerbillus*, *Taterillus*). Counter-shading is generally pronounced, the dorsal pelage is pale sandy to saturated brown, and the ventral pelage is white. The expanded auditory bullae impart a relatively large and wide shape to the head. Pinnae are small, rounded and well furred in many species,

or larger, ovate and sparsely covered in some, especially the taterillines *Gerbillus* and *Taterillus*; conspicuous white to buffy postauricular patches occur in some (*Desmodilliscus*, *Pachyuromys*). The elongated metatarsal bones of the hindfoot reflect the running and semi-saltatory locomotion of most species, although none is strictly bipedal as in the dipodids *Allactaga* and *Jaculus*. The plantar surface is naked, moderately furred, or so densely furred as to obscure the plantar pads. The tail may be longer than, or about equal to the head and body, or notably shorter (as in *Desmodilliscus* and *Pachyuromys*); it is moderately to densely haired in most forms, with a terminal black pencil or tuft in some species (*Taterillus* and *Meriones*). A mid-ventral sebaceous gland is present in many species, and is especially well-developed in ♂♂. There are eight nipples (arranged as pectoral, post-axillary and two inguinal pairs) or six nipples (pectoral pair absent).

The head and postcranial skeleton exhibits diagnostic traits of the subfamily: supraorbital shelf present and well developed; zygomatic plate broad and dorsal notch deep; lacrimal enlarged, forming a conspicuous ledge over the anterior orbit; mesopterygoid fossa narrowly V-shaped and parapterygoid fossae compressed and cavernous; anterior palatal foramina and posterior palatine foramina extremely long and slit-like; optic foramen as large as sphenoidal fissure; stapedia foramen present, penetrating the wall of the tympanic bulla rather than the petrotympanic fissure; sphenofrontal foramen and accessory foramen ovale absent (except *Tatera*); angular process of mandible deflected laterally; auditory bullae inflated, both ectotympanic and mastoid chambers, and malleus of the perpendicular type; entepicondylar foramen present (except *Tatera*); scapula with third scapular fossa; vertebral column with 12 thoracic vertebrae and seven lumbar vertebrae (Lay 1972, Carleton 1980, Pavlinov 1980, Carleton & Musser 1984, Pavlinov *et al.* 1990). In all African species, the molars are rooted, anchored by accessory rootlets in most species, and their occlusal pattern is lophate, planar or prismatic; protoconulid present on M₁, distinct from or fused with anteroconid; M₃ greatly reduced and cylindriciform, the posterior lamina (hypoconid and entoconid) of M₃ absent; upper incisors with single groove (smooth in *Psammomys*) (Ellerman 1941, Rosevear 1969, Pavlinov 2001). Other notable characters of those Gerbillinae studied include: the glans penis is of the complex type; preputial glands are generally absent, remainder of accessory reproductive gland of ♂ is complete; the stomach is single-chambered and hemiglandular; and the stapedia artery lacks supraorbital and mandibular branches, the orbital blood supply instead is formed by the infraorbital branch (Arata 1964, Vorontsov 1967, Bugge 1970).

Morphology of the auditory bullae has figured prominently in the taxonomic and phylogenetic understanding of gerbilline rodents (Lay 1972, Pavlinov 1980, Pavlinov *et al.* 1990). Evolutionary increases in pneumatization of the mastoid portion are especially significant and have given rise to spectacular middle ear anatomies, such as those that characterize *Pachyuromys duprasi* and *Meriones crassus*. Enlargement of the middle ear chambers lessens impedance of air space behind the tympanic membrane and thereby enhances sensitivity to relatively low sound frequencies (Lay 1972, 1993, Webster & Webster 1984). These volumetric adaptations – coupled with modifications in the ossicular lever system, expanded surface area of the tympanic and accessory tympanic membranes, and acoustic specializations of the inner ear – constitute a clever predator-detection system for animals

Figure 44. Structure of the auditory bulla in several genera of Gerbillinae to show relative and comparative sizes of tympanic bulla and mastoid. (a) *Arvicanthis niloticus* (Murinae) without any enlargement of auditory bulla, (b) *Gerbillus*, (c) *Microdillus*, (d) *Gerbillus*, (e) *Meriones*, (f) *Sekeetamys*, (g) *Desmodilliscus*, (h) *Pachyuromys*. Dark stipple = tympanic bulla. Light stipple = mastoid. Arrows indicate position of occipital condyles (not visible in lateral view). Variations between genera include size of tympanic bulla and mastoid (relatively and comparatively), size of bulla in relation to GLS, and position of posterior end of auditory bulla to the posterior end of the occipital condyles (see text for further details). Species within a genus may show slight variation to the generalized genus condition shown here. The condition in Dipodidae (*Allactaga*, *Jaculus*) is similar to that of *Desmodilliscus*. (Based on original illustration by D. C. D. Happold.)

living in open environments and must have contributed importantly to the ecological successes of the subfamily (Lay 1972). Indeed, the Gerbillinae contains more species indigenous to the great Saharo-Gobian realm of Africa and Asia than any other group of Rodentia (Petter 1961, Lay 1991, Shenbrot *et al.* 1999b). Parallel changes in middle ear anatomy characterize other rodent lineages that have radiated within desert and semi-arid biomes, in both North America (Heteromyidae) and Afro-Asia (Dipodidae) (Figure 44).

Although morphological evidence supporting the monophyly of Gerbillinae is substantial (Carleton & Musser 1984, Pavlinov *et al.* 1990), their phylogenetic stature as a subfamily of Muridae is a relatively recent apprehension, stemming from both palaeontological and molecular investigations. Gerbils were traditionally grouped with the Cricetidae in those classifications that maintained Muridae and Cricetidae as separate families (e.g. Miller & Gidley 1918, Simpson 1945, Misonne 1974), or accorded their own family status as Gerbillidae (Tullberg 1899, Chaline *et al.* 1977, Pavlinov *et al.* 1990). Phyletic interpretations of nuclear and mitochondrial DNA sequences, however, cladistically affiliate gerbillines with murines and deomyines (Martin *et al.* 2000, Michaux & Catzeflis 2000, Michaux *et al.*, 2001). Using molecular-clock estimates, Michaux *et al.* (2001) suggested that the divergence of Gerbillinae occurred during the early to middle Miocene, about 18 to 16 mya years ago.

Such divergence times are wholly reasonable in the context of the rich fossil history of gerbils. Their origin is convincingly linked to myocricetodontines, an extinct group known from the Miocene of both Africa and Asia and believed to represent the ancestral stock of the subfamily (Jaeger 1977b, Tong 1989, Lindsay 1994, Wessels 1996). Tong & Jaeger (1993) suggested that the Murinae were also derived from an early myocricetodontine, with the split between the two groups transpiring around 16 mya years ago. The oldest true gerbilline so far known from Africa is *Protatera*, from the late Miocene of Morocco (Jaeger 1977b); representatives of living genera appear in the late Pliocene and are commonplace in Pleistocene faunas (e.g. Lavocat 1978, Denys 1987a, 1989a, Senut *et al.* 1992, Avery 1998).

Generic interrelationships are relatively well understood, as set forth in the comprehensive monograph of Pavlinov *et al.* (1990, see also Pavlinov 2001), which serves as the basis for recognizing the following tribes (-ini) and subtribes (-ina) among African genera

(ranks as adapted by McKenna & Bell 1997). Here (in contrast to Musser & Carleton 2005), *Dipodillus* is considered as a synonym of *Gerbillus* (see *Gerbillus* profile) and hence 12 genera (Table 22) are recognized as follows:

- Taterillini: Gerbillurina (*Desmodillus*, *Gerbillurus*); Taterillina (*Gerbilliscus*, *Taterillus*).
- Ammodillini: (*Ammodillus*).
- Gerbillini: Desmodilliscina (*Desmodilliscus*); Gerbillina (*Gerbillus* [including *Dipodillus*], *Microdillus*); Pachyuromyina (*Pachyuromys*); Rhombomyina (*Meriones*, *Psammomys*, *Sekeetamys*).

The profiles for each genus, and for each species within each genus, are given alphabetically, not by their tribal and subtribal affiliations.

Michael D. Carleton & Guy G. Musser

GENUS *Ammodillus*
Ammodile

Ammodillus Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 102. Type species: *Gerbillus imbellis* de Winton, 1898.

Ammodillus is a monotypic genus found only in Somalia. It is very similar to *Gerbillus*, and distinguished from *Gerbillus* by special skull characters (especially the lack of a coronoid process on the mandible, and the posterior convergence of the upper cheekteeth). Characters

of the genus are given in the species account below. The only species is *Ammodillus imbellis*.

^a A few species of *Gerbillus* have a mean HB of less than 80 mm (*G. brockmani* 78 mm; *G. juliani* 63 mm; *G. henleyi* 65 mm; *G. nanus* 72 mm).

^b Cuspidate but often laminate in older animals, with transverse sets of cusps joining to form single transverse occlusal surface.

^c Formerly *Tatera*.

^d Shallow grooves may extend anteriorly to posterior end of anterior palatal foramina.

Ammodillus imbellis AMMODILE (WALO)

Fr. Ammodile; Ger. Walo

Ammodillus imbellis (de Winton, 1898). Ann. Mag. Nat. Hist., ser. 7, 1: 249. Goodar, Somalia.

Ammodillus imbellis.

Taxonomy Originally described in the genus *Gerbillus*, but later placed in a new genus, *Ammodillus* (see below). Synonyms: none. Chromosome number: 2n = 18 (Capanna & Merani 1981).

Description Small gerbil with a long tail ending in a brown pencil. Dorsal pelage reddish-fawn to brownish-yellow; hairs grey at base, with reddish fawn terminal band and black tip. Flanks paler and clearer. Ventral pelage white. Hairs of eyebrows, cheeks and upper surface

of forelimbs tipped with grey. White supraorbital and postauricular patches. Fore- and hindfeet white. Soles of hindfeet naked. Tail very long (ca. 145% of HB), dark above, paler below, slightly haired; brown hairs (8–10 mm long) on terminal one-third of upper surface form conspicuous pencil. Two skull characters are unique: the molar rows converge posteriorly (more so than in any other genus of the gerbils) and tend to be laminate rather than cuspidate, and there is no coronoid process on the mandible (Roche & Petter 1968, Funaioli 1971 in Nowak 1999). Incisors strongly opisthodont (Figure 45). Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

Gerbillus brockmani. Smaller (HB: 71–84 mm).
G. somalicus. HF shorter (24–25 mm. Neither of these species has the skull characters of *Ammodillus* noted above.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded only from Somalia and E Ethiopia.

Habitat In S Somalia, found in coastal steppe (Capanna & Merani 1981). In E Ethiopia, found ‘in sandy soil close to wells’ at Gerlogobi (Thomas 1904a). Digs burrows in sandhills (near El Bur).

| | Pencil at tip of tail | Notes |
|--|--------------------------|---|
| | Absent | Sahel Savanna Zone; Mauritania to Chad |
| | Absent | Somalia |
| | Small to well-developed | Widespread in North, West and East Africa |
| | Absent to well-developed | South Africa, Namibia |
| | Well-developed | Somalia, Ethiopia |
| | Absent | North Africa |
| | Absent | South-West Arid BZ |
| | Well-developed | Widespread in savannas of West, central and East Africa north of Rainforest Zone |
| | Very well-developed | NE Africa |
| | Present | North Africa |
| | Absent to well-developed | Widespread in semi-arid and savanna habitats south of Sahara. Slight groove on each upper incisor |
| | Small | North Africa. Slight groove on each upper incisor |

Figure 45. Skull and mandible of *Ammodillus imbellis* (MZUF M4940).

Abundance Very rare. Only known from a few specimens from seven localities.

Remarks The lack of a coronoid process on the mandible results in a weak bite (Nowak 1999); this suggests that *Ammodillus* can only eat soft foods. No information on diet. Found in small colonies on sandhills (A. Simonetta pers. comm.). Individuals are recorded to fight amongst themselves (Nowak 1999). One specimen was obtained from the stomach of a viper (*Bitis* sp.).

Conservation IUCN Category: Data Deficient.

GENUS *Desmodilliscus*

Brauer's Dwarf Gerbil

Desmodilliscus Wettstein, 1916. Anz. Akad. Wiss. Wien 53: 153. Type species: *Desmodilliscus braueri* Wettstein, 1916.

Desmodilliscus is a monotypic genus endemic to Africa, distributed throughout the Sahel Savanna BZ from Mauritania and Senegal to Sudan. The characters of the genus are those given below in the species account. The small overall size and the relatively short tail are the main external characters, but skull shape and reduction in the

number of cheekteeth (3/2) are unique among the Muroidea. Dental formula: I ¹/₁, C ⁰/₀, P ⁰/₀, M ³/₂ = 14.

L. Granjon

Desmodilliscus braueri BRAUER'S DWARF GERBIL (POUCHED GERBIL)

Fr. Gerbille naine de Brauer; Ger. Brauers Zwergrenmaus

Desmodilliscus braueri Wettstein, 1916. Anz. Akad. Wiss. Wien 53: 153. South of El Obeid, Sudan.

Taxonomy Setzer (1969) recognized three subspecies, but Rosevear (1969) and Hutterer & Dieterlen (1986) stated there was morphological homogeneity throughout its range. Synonyms: *buchanani*, *fuscus*. Subspecies: none. Setzer (1969) recognized three subspecies, but Rosevear (1969) and Hutterer & Dieterlen (1986) indicated that there is morphological homogeneity throughout the range and therefore no subspecies are recognized here. Chromosome number: 2n = 78, aFN = 104 (Senegal; Granjon *et al.* 1992).

Description Very small gerbil. Dorsal pelage sandy-grey; hairs blackish-grey at base, with sandy subterminal band and minute dark tip, giving a speckled and relatively dark effect. Hairs of the flanks white at base with sandy tip. Ventral pelage entirely white. Head relatively large with short ears, big eyes and white cheeks. White stripe above and behind the eyes, and white postauricular patch. Hindfeet slender; forefeet with a slight covering of short white hairs; soles of hindfeet naked. Tail short (ca. 65–75% of HB), covered with short hairs, but without any pencil. Skull: incisor teeth with curved

Desmodilliscus braueri.

front face, each with single deep groove situated laterally; very inflated tympanic bullae and mastoids that extend well posteriorly to the occipital condyles; palate broad; posterior palatal foramina very wide extending anteriorly to M¹ and to within about 1 mm of the anterior palatal foramina. Unique in possessing only two molars on the mandible (see genus profile above) (Figure 46). Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species No other species of gerbil has such a small head and body length (Table 22), and no other species of gerbil has only two cheekteeth in each ramus of the mandible.

Distribution Endemic to Africa. Sahel Savanna BZ. Widespread, most records being between 12°N and 18°N. Recorded from Mauritania and Senegal to Sudan, through Mali, Burkina, Niger, Nigeria, N Cameroon and possibly Chad (Heim de Balsac 1967b, Hutterer & Dieterlen 1986). Geographic range may be extending southwards, due to desertification (Duplantier *et al.* 1997).

Habitat Scrub savannas with sparse vegetation, especially on indurate sandy or sandy-clay soils, often with gravel. In Senegal, found in the northern *Acacia*-savanna, receiving an annual rainfall of 200–500 mm (Heim de Balsac 1967b, Poulet 1984).

Abundance Probably common to very abundant in suitable habitats (although difficult to catch in traps). Common in owl pellets in some localities of N Mali (Heim de Balsac 1967b). Dozens of these gerbils seen during a few hours of night driving in NW Mali in Nov 1999 (L. Granjon & B. Sicard unpubl.). Said to be much less abundant than syntopic *Taterillus* in N Senegal, with an estimate of 2–4 individuals/ha (at maximum) (Poulet 1984); in the same region, its abundance may vary inversely with that of other rodents, i.e. high during droughts and low after heavy rainfalls (Poulet 1978).

Adaptations Terrestrial and nocturnal. Lives in a small, shallow, but complex burrow with up to 13 entrances, possibly inhabited by groups of individuals (N Senegal; Poulet, 1984).

Foraging and Food No information.

Social and Reproductive Behaviour Most probably a social, or even colonial, species (Poulet 1984).

Figure 46. Skull and mandible of *Desmodilliscus braueri* (BMNH number not recorded).

Desmodilliscus braueri

Reproduction and Population Structure In captivity, reproduction observed only between Jun and Aug in Senegal (corresponding to the end of dry season and beginning of wet season). Gestation: 26 days. Litter-size: 2 and 3 (n = 8 litters). Weight at birth around 0.9 g. Weaned at 28 days, at a weight of 3–4 g (Poulet 1984).

Predators, Parasites and Diseases Locally preyed on extensively by Barn Owls *Tyto alba* (Heim de Balsac 1967b, Poulet 1984). Also preyed on by wild cats, foxes and snakes (e.g. *Eryx mulleri*; Poulet 1984).

Conservation IUCN Category: Least Concern.

GENUS *Desmodillus* Cape Short-tailed Gerbil

Desmodillus Thomas and Schwann, 1904. Abstr. Proc. Zool. Soc. Lond. 1904 (2): 6. Type species: *Gerbillus auricularis* Smith, 1834.

Desmodillus auricularis.

Monotypic genus widespread in the South-West Arid BZ. The genus is characterized by small size (mean HB 110 mm), short tail (mean 84 mm and shorter than head and body) without any pencil or tuft, and short ears. Skull characters include very large tympanic bullae that extend posteriorly to the occiput, short zygomatic plate, long slender incisors each with a shallow groove. M¹ has three rows of cusps, M² has two rows of cusps, M³ has single cusp (Figure 47). The form of the bullae is quite different to that of *Gerbillus* and *Gerbilliscus* (formerly *Tatera*) (see Figure 44). Although larger than sympatric *Gerbillus*, it is smaller than *Gerbilliscus* (formerly *Tatera*) in southern Africa. Fossil forms have been found back to the Pleistocene

Figure 47. Skull and mandible of *Desmodillus auricularis* (BMNH 25.1.2.76).

in South Africa (Avery 1998) and Namibia (Senut *et al.* 1992, Musser & Carleton 2005). The single species is *Desmodillus auricularis*.

Jan A. J. Nel

Desmodillus auricularis CAPE SHORT-TAILED GERBIL (NAMAQUA GERBIL)

Fr. Gerbille à queue courte; Ger. Kurzschwanz-Rennmaus

Desmodillus auricularis (Smith, 1834). S. Afr. Quart. J., ser. 2, 2: 160. Kamiesberg, South Africa.

Taxonomy Originally described in the genus *Gerbillus*. Synonyms: *brevicaudatus*, *caffer*, *hoeschi*, *pudicus*, *robertsi*, *shortridgei*, *wolffi*. Subspecies: none. Chromosome number: $2n = 52$.

Description Small, stockily built gerbil with fine, soft, dense pelage. Dorsal pelage variable, ochrous-orange to tawny-brown; hairs slate-grey at base, ochrous-yellow in middle, with dark tip on some hairs. Ventral pelage, including chin and throat, pure white. Head large, with thickened nose, long black vibrissae and large eyes. Ears small, oval and flesh-coloured. Distinctive white postauricular patch; smaller less conspicuous supraorbital and suborbital patches. Fore- and hindlimbs short and thick, with short white hairs on upper surfaces of feet; four digits on forefeet, five on hindfeet; hindfeet with hairy soles. Tail of moderate length (ca. 75–80% of HB), same colour as dorsal pelage (with dark tip in darker coloured individuals); without pencil. Skull characterized by the greatly enlarged auditory bullae (ca. 41% of GLS, larger as percentage of GLS than in most other gerbillines). Nipples: $2 + 2 = 8$. Females weigh on average 20% less than ♂♂.

Geographic Variation None recorded.

Similar Species *Gerbillurus* spp. Smaller mean head and body length; tail longer (absolute and as percentage of HB length); pencil at end of tail (in some species); smaller bullae (ca. 30% of GLS).

Distribution Endemic to Africa. South-West Arid BZ (Kalahari and Namib Deserts, Karoo) and peripherally in the extreme south of the Zambezi Woodland and South-West Cape BZs. Widely distributed in Namibia (except NE), Botswana (except N and parts of E), arid parts of South Africa, and marginally in SW Angola. Recorded from near sea level to ca. 1600 m (extrapolated from distribution map in De Graaff 1981).

Habitat Favours calcareous ground, fine soils or consolidated sand (sometimes covered in pebbles) with a sparse cover of grass or low shrub. In the southern parts of the Kalahari and Little Namaqualand, more common in calcareous ground or outcrops and fringes of pans. Avoids dense grassland or thick scrub.

Abundance Common in suitable habitat. Comprises 4.95–5.5% of small mammals in SW Kalahari (Nel & Rautenbach 1975, J. A. J. Nel unpubl.), but with clear differences in abundance in different micro-habitats and at different times (Nel 1978). Large fluctuations in numbers rarely occur.

Adaptations Nocturnal and terrestrial. Locomotion is non-saltatorial. The greatly enlarged auditory bullae afford acute hearing and probably allow gliding owls to be located (Lay 1972). Burrows are extensive and complicated with 1–7 openings, blind alleys and storage chambers; they are 300–600 mm deep (sometimes deeper) and burrow diameter is ca. 53 mm (Nel 1967, Smithers 1971). At

*Desmodillus auricularis*

ambient temperatures of 11–30 °C, deep body temperature (T_b) can be kept nearly constant (varies by 0.5 °C in ♂♂, 0.1 °C in ♀♀) (Nel & Rautenbach 1977). Renal concentrating ability is very good (urine concentration up to 6.1 mOsmol/kg), and evaporative water loss at low relative humidity is very low (Christian 1978, 1979b, Buffenstein *et al.* 1985). These gerbils are independent of free water, and this allows breeding at times when other sympatric species are reproductively inactive (Christian 1979b). They can also store fat in the tail when conditions are good; hence some older individuals are very large, perhaps being in their second year.

Foraging and Food Omnivorous. Food includes seeds, annuals, seeds of wild melons, and insects. In winter, diet is mostly seeds and in summer it changes to insects and green leaves (in nearly equal amounts). Gerbils forage and feed up to 30 m from burrows. Food may be stored in burrows ('larder hoarding') and also other locations within the home-range ('scatter-hoarding').

Social and Reproductive Behaviour Asocial and solitary, although burrows can be close together and linked with pathways. In captivity, ♀♀ are dominant over ♂♂ and may kill and consume them, as well as other ♀♀. Males are tolerated by ♀♀, for a short period only, at times of copulation.

Reproduction and Population Structure Under favourable conditions, reproduction can occur throughout the year, but births are mostly during the hot wet season. Gestation: 21 days. Mean litter-size for ♀♀ caught in the wild: 2 ($n = 5$) in S Kalahari (Nel

& Stutterheim 1973) and 4 ($n = 19$) elsewhere (Keogh 1973). Mean weight of young at birth 1.84 g ($n = 10$) in the Kalahari and 4.4 g ($n = 19$) elsewhere. Nipple-clinging absent. Young naked and blind at birth. Ear pinnae free at Day 12. Eyes open Day 21. External auditory meatus open Day 23. Crawling starts Day 2; walking Day 15; grooming Day 24; digging and sand-bathing Day 30. Sucking ceases at Day 33 (Nel & Stutterheim 1973). In SW Kalahari, young enter the population towards the end of the wet season (Feb–Apr). Populations peak in mid-winter (Jun–Aug) and decline thereafter.

Predators, Parasites and Diseases Main predators include Barn Owls *Tyto alba*, Spotted Eagle-owls *Bubo africanus* and snakes (e.g. cobra, *Naja nivea*). Ectoparasites include 24 species of fleas (many involved in transmitting plague to man), mites and ticks (details in De Graaff 1981). Dwarf Gerbils are vectors of bubonic plague, and in the laboratory can become infected with listeriosis, louse typhus, murine or rat typhus and tick-bite fever (De Graaff 1981).

Conservation IUCN Category: Least Concern.

GENUS *Gerbilliscus*

Gerbils

Gerbilliscus Thomas, 1897. Proc. Zool. Soc. Lond. 1897: 433. Type species: *Tatera boehmi* (Noack, 1897).

The genus *Gerbilliscus* comprises 12 species, which are widely distributed in all sub-Saharan Africa with the exception of the Rainforest BZ, and they occupy a variety of habitats in both northern and southern savannas. *Gerbilliscus leucogaster*, *G. brantsii* and

G. validus are widespread and common in southern and eastern Africa; other species have less extensive distributions (*G. afra*, *G. gambiana*) and one species is very restricted (*G. phillipsi*).

Gerbilliscus, previously considered as a subgenus of *Tatera*, is now elevated to genus rank, to account for differences between true *Tatera* (represented by the sole Asian species *T. indica*) and the African species (Pavlinov *et al.* 1990, Pavlinov 2001, G. Musser pers. comm.). These differences are mainly in dental pattern and mastoid bone structure (more derived in *Gerbilliscus* than in *Tatera*), but also include humerus morphology and diploid number of chromosomes ($2n = 68$ in *Tatera*, $2n = 36$ to 52 in *Gerbilliscus*).

The species of *Gerbilliscus* are on average more powerfully built than species from the other genera of Gerbilline rodents; they generally have a darker pelage, although there is considerable geographic variation in colour of the dorsal pelage. Populations in arid to semi-arid habitats have paler colouration than populations in moister habitats. They have comparatively long hindfeet, and the soles are naked. The skull is robustly built, and the molar row is larger than in *Taterillus*. The auditory bullae are inflated anteriorly with a small posterior section, in contrast to *Gerbillurus* and *Desmodillus* in which the posterior section is also inflated. Posterior palatal foramina are short (no longer than 3 mm, and considerably shorter than in *Taterillus*), a feature considered diagnostic among the Gerbillinae by Davis (1975a) (Figure 48).

The species of *Gerbilliscus* are physiologically, morphologically and behaviourally adapted to living in dry environments. They are terrestrial and nocturnal, spending the daytime in burrows that can be complex and deep. They are predominantly granivorous, but may

Figure 48. Skull and mandible of *Gerbilliscus kempi* (HC 1321).

Table 23. Species in the genus *Gerbilliscus*. Arranged in order of increasing mean head and body length.

| <i>G. afra</i> | Reddish-brown; evenly coloured throughout | 141.3 (124–157) | 110% | 39.1 (34.3–42.0) | Opisthodont; single groove | 2n = 44, FN = 66 | SW South Africa only |
| <i>G. phillipsi</i> | Pale orange-brown above, white below; some black hairs above towards terminal end; without pencil | 144.0 (143–145) | 130% | 38.9 (37.3–40.9) | Opisthodont; single groove | n. d. | N Kenya, Ethiopia |
| <i>G. guineae</i> | Dark above, white below; small black terminal tuft | 149.8 (128–178) | 110–140% | 36.2 (33.1–38.7) | Opisthodont; single groove | 2n = 50, FN = 64 | Senegal to Togo |
| <i>G. robustus</i> | Mostly brown above, usually pale or brown below; some individuals with black at tip or along most of length | 152.2 (120–190) | 115% | 41.9 (39.0–44.7) | Opisthodont; single well-defined groove | 2n = 40, FN = 70 | NE Africa |
| <i>G. inclusus</i> | Dark above, white below; occasionally with white tip | 156.0 (152–161) | 115% | 41.1 (36.7–44.3) | Opisthodont; deep single groove | n. d. | Tanzania, Mozambique, Zimbabwe |
| <i>G. kempfi</i> | Dark above, white below; small dark pencil | 158 (140–190) | 100% | 40.2 (38.7–41.6) | Opisthodont; single groove | 2n = 36 | Senegal to Cameroon |
| <i>G. boehmi</i> | Upper half/two-thirds dark brown, terminal half white; with pencil | 162.3 (139–179) | 130% | 43.5 (42.0–45.2) | Opisthodont; two faint grooves | n. d. | East-central Africa |
| <i>G. validus</i> | Brown above, pale below; without terminal pencil | 167 (135–195) | 95% | 41.7 (38.5–44.7) | Opisthodont; usually smooth without groove | n. d. | Angola, S and E DR Congo, Zambia, Tanzania, Uganda, Sudan and W Ethiopia. |
| <i>G. gambianus</i> | Dark above, orange-brown on sides, white below; without pencil | 168.2 (148–196) | 80–100% | 37.2 (34.0–40.7) | Opisthodont; single groove | 2n = 52, FN = 64 | Senegal, Mali, Niger, Chad |
| <i>G. nigricaudus</i> | Black above, black below; white hairs below near base of tail in some individuals | 185.8 (178–193) | 110% | 48.7 (47.0–50.5) | Opisthodont; single well-defined groove | n. d. | NE Africa |

eat a variety of food including insects, according to availability. They can be locally abundant and, in agricultural areas, may cause damage to crops. They are important vectors of fleas that carry plague.

The taxonomy of the genus is uncertain, because important intraspecific morphological variation masks the distinction between species. One species, *G. boehmi*, has been placed in the subgenus

Gerbilliscus gerbils.

Gerbilliscus on account of its double-grooved incisors and fringed, white-tipped tail; all the other African species are included in the subgenus *Taterona*. In the subgenus *Taterona*, the species have sometimes been distributed between an 'afra' and a 'robusta' group, the systematic status of which is questionable. *Gerbilliscus afra*, *G. brantsii* and *G. inclusus* are placed in the 'afra' group, and are distinguished from the 'robusta' group on the grounds of the quality of pelage, and morphological and craniological characters; however, there is some overlap between these subgeneric characters. Chromosomal and molecular data support the close relationship between *G. afra* and *G. brantsii*, but (on present evidence) do not support a monophyletic 'robusta' group.

Criteria used to distinguish between species include morphological and biometrical characters (colour, overall size, tail length, presence and size of terminal pencil on the tail, skull size and characters), as well as differences in karyotypes. Considerable geographic variation within species, and overlap in distinguishing characters between species makes precise identification difficult in some cases. Geographic locality aids identification, but two or more species of *Gerbilliscus* may occur sympatrically and syntopically in parts of the distribution range. Twelve species recognized: *G. afra*, *G. boehmi*, *G. brantsii*, *G. gambianus*, *G. guineae*, *G. inclusus*, *G. kempfi*, *G. leucogaster*, *G. nigricaudus*, *G. phillipsi*, *G. robusta* and *G. validus* (Table 23).

L. Granjon & Edith R. Dempster

Gerbilliscus afra CAPE GERBIL

Fr. Gerbille du Cap; Ger. Kap-Nacktsohlen-Rennmaus

Gerbilliscus afra (Gray, 1830). Spicilegia Zool. 2: 10. Cape of Good Hope, South Africa.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Synonyms: *africanus*, *caffer*, *gilli*, *schlegelii*. Subspecies: none. Chromosome number: $2n = 44$, $FN = 66$ (as *T. afra*); karyotype identical to that of *G. brantsii* (Qumsiyeh 1986).

Description Medium-sized gerbil with white underparts, darker dorsal surface and long tail. Dorsal pelage reddish-orange or pale buffy, faintly grizzled with dark brown; hairs dull lavender at base, reddish-orange or pale buff at tip. Hairs fairly long and broad, with chevron scale pattern. Flanks similar to dorsal pelage. Ventral pelage and inside of limbs white, with clear delineation between colour of flanks and ventral pelage. Head narrow, with pointed nose, long vibrissae, sides of muzzle white. Large eyes. Ears elongated, pale flesh colour inside, dark brown outside, rounded at tips. Outer surface of limbs reddish-orange; hindlimbs much longer than forelimbs; hindfeet elongated. Fore- and hindfeet white, five digits each, Digit 5 on forefeet reduced. Tail long (ca. 110% of HB),

covered with dense short hairs, same colour or slightly paler than dorsal pelage and coloured evenly to tip. Nipples: $2 + 2 = 8$, but considerable variation. Front face of each upper incisor with groove, lower incisors ungrooved; molar teeth broader and heavier than *G. leucogaster*. Auditory bullae not particularly enlarged. Males on average larger than ♀♀.

Geographic Variation None recorded.

Similar Species

G. brantsii. Ventral pelage white; tip of tail white; more widespread; allopatric.

G. leucogaster. Molar teeth narrower; auditory bullae not markedly inflated; allopatric.

Distribution Endemic to Africa. South-West Cape BZ. Recorded in Western and Northern Cape Provinces of South Africa, from

Nieuwoudtville in Northern Cape southwards to Cape Peninsula and eastwards coastally to Herold's Bay.

Habitat Confined to areas of loose, sandy soils or sandy alluvium. Common in cultivated lands.

Abundance Common in suitable habitats.

Adaptations Nocturnal and terrestrial. Moves by quadrupedal saltation. Excavates extensive burrows in sandy places. Numerous interconnecting tunnels end in a chamber containing nest of shredded vegetation.

Body temperature maintained at 34–36°C at Ta of 10–30°C, but susceptible to hyperthermia at Ta above 30°C. No significant drop in Tb at 5°C, indicating good tolerance of low temperatures. Water turnover rate higher than other species of southern African gerbils and probably associated with living in a mesic environment. Basal metabolic rate higher than average for gerbilline rodents, a condition that is probably related to the mesic environment, herbivory and tolerance of a relatively low ambient temperature (Duxbury & Perrin 1992).

Foraging and Food Herbivorous, and occasionally insectivorous. Cape Gerbils eat grass, bulbs, roots and seeds. Captive animals also eat insects.

Social and Reproductive Behaviour Social structure unknown. Adults rarely aggressive in laboratory encounters (Dempster *et al.* 1993). Copulation consists of series of mounts with and without intromission, culminating in intromission with ejaculation. No lock; copulatory plug deposited after ejaculation. Several bouts of mounting with and without ejaculation occur over about one hour.

Vocalizes audibly with calls of 1.6–5.3 kHz, with second to sixth harmonics. Ultrasonic whistles emitted in frequency range 20–34 kHz. Whistles are short (duration <225 msec) or long (duration >225 msec) (Dempster & Perrin 1994).

Reproduction and Population Structure In SW Cape Province, South Africa, ♀♀ have a breeding season of eight months (Aug to end Mar) followed by four months of anoestrus when there are no pregnancies and during which none of the young ♀♀ reach puberty (Measroch 1953). Males cease spermatogenesis and ♀♀ are anoestrus during the cool wet season. Breeding strategy is similar to other gerbil species: short gestation, large litter-size, altricial young, iteroparous. Embryo number: 4.0 (2–6). Litter-size: 4 (range 3–5). Mean weight at birth: 4.1 g. Growth rate in first 28 days: 0.8 g/day. Pups cling to nipples from 1 to 4 days old. Incisors erupt Day 10. Dorsal pelage visible Day 6–8. Eyes open Day 18–21. Weaned by Day 22–28. Females experience a postpartum oestrus (Dempster *et al.* 1992).

The population is mostly subadults Jan–Mar, mostly adults from Jul–Nov. Males and ♀♀ may survive to a second breeding season, with an estimated life-span of 12–17 months. During the breeding season, 60% of ♀♀ are pregnant. Females in the wild may have six to seven litters in one year (Measroch 1953). Testes in adult ♂♂ are unusually large, comprising over 8% of adult body weight (Allanson 1958).

Predators, Parasites and Diseases No information available on predators. Susceptible to infections of *Mycobacterium tuberculosis*, louse

Gerbilliscus afra

typhus caused by *Rickettsia prowazekii*, rat typhus caused by *R. typhi*, and tick-bite fever by *Rickettsia conorii*. Ectoparasites include mites of the families Laelaptidae (9 spp.), Myobiidae (1 sp.), Trombiculidae (2 spp.) and Listrophoridae (1 sp.); and fleas of the families Pulicidae (9 spp.), Hystricopsyllidae (1 sp.) and Chimaeropsyllidae (1 sp.). Like *G. brantsii*, afflicted by *Yersinia pestis*, which may lead to local outbreaks of bubonic plague (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Although formerly listed in the South African Red Data Books, Smithers (1986b) recommended that it should be removed because it is not uncommon, adapts well to changing land use, and population numbers do not seem to have declined.

Edith R. Dempster

Gerbilliscus boehmi BOEHM'S GERBIL

Fr. Gerbille de Boehm; Ger. Boehms Nacktsohlen-Rennmaus

Gerbilliscus boehmi (Noack, 1887). Zool. Jahrb. Syst., 2: 241. Qua Mpala, Marungu, S DR Congo.

This locality has been stated to be in N Zambia (see Ansell 1978, Bates 1988).

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Synonyms: *fallax*, *fraterculus*, *varia*. Subspecies: none. Chromosome number: not known.

Description Large dark-coloured gerbil with very long white-tipped tail. Dorsal pelage medium brown, flecked with black and ochre, darker on midline than on flanks; hairs medium grey at base, with black tip (mid-dorsally) or ochre tip (flanks). Ventral pelage white; sharp delineation between colour of flanks and ventral pelage. Hairs of cheeks and shoulders often tipped with cinnamon. Forehead and nasal region dark brownish-black. Eyes large. Ears large, rounded, with short black hairs. Chin, inner surface of limbs white. Soles of hindfeet naked and darkly pigmented. Tail very long (ca. 130% of HB), thin; proximal half or two-thirds with short hairs, dark above, white below; terminal half or third pure white above and below, often with small pencil of white hairs. Skull: large and deep; incisors orthodont, sometimes with two faint longitudinal grooves on each upper incisor tooth; cheekteeth broad, laminate and relatively long. Nipples: $2 + 1 = 6$ or $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

Gerbilliscus leucogaster, *G. validus*, *G. robustus*, *G. nigricaudus*. All have shorter tails (actual and relative to HB) without white tip.

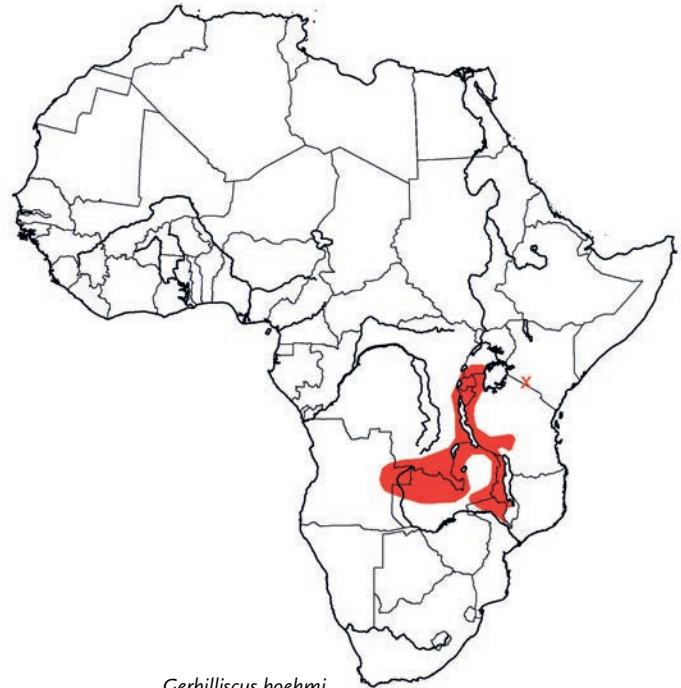

Distribution Endemic to Africa. Zambezian Woodland BZ, especially northern part. Widespread in savanna woodlands (mostly at 1000–2000 m) from SW Kenya and S Uganda to N Mozambique, Malawi, S DR Congo and W Zambia. Probably also present in Moxico Province of E Angola. Not known from east of L. Malawi or from the lowland areas of the Luangwa Valley in Zambia.

Habitat *Brachystegia* woodland, mostly at higher altitudes, where there is good cover of grass and herbaceous plants; also in grassy plains (Uganda) and 'bush' habitats. Prefers moister habitats (cf. *G. leucogaster*). Individuals found in old banana plantations (Misonne 1965a) and old millet fields (Kingdon 1974) in some parts of range.

Abundance Although widespread, mostly uncommon or rare. Reasons for rarity not known.

Adaptations Nocturnal. Burrows have one or two entrances and are not marked by a pile of excavated soil. Sometimes use burrows of other *Gerbilliscus* spp., or those of mole-rats (*Cryptomys* spp.) (Vesey-Fitzgerald 1966). Habitat and altitudinal range suggest that moderate climatic temperatures are required for survival.

Foraging and Food Omnivorous, primarily vegetable material and insects (Hanney 1965, Misonne 1965a).

*Gerbilliscus boehmi*

Social and Reproductive Behaviour Mostly unknown. May forage over a large area (Vesey-Fitzgerald 1966). In some localities, lives parapatrically with *G. validus* (Tanzania; Kingdon 1974), *G. leucogaster* (Malawi: Hanney 1965), and with *Lemniscomys* sp. and sengis (Kagera N. P., Rwanda; Misonne 1965a).

Reproduction and Population Structure Breeding recorded in early wet season (Nov) and end of wet season (May). Lactating ♀♀ in Nov (Zambia) and May (Malawi); pregnant ♀ in May (Rwanda). Embryo number: 5 ($n = 1$; Hanney 1965, Misonne 1965).

Predators, Parasites and Diseases Preyed upon by owls at several locations in Kagera N. P., Rwanda (Misonne 1965) and at Dedza, Malawi (Hanney 1965).

Conservation IUCN Category: Least Concern.

Gerbilliscus brantsii HIGHVELD GERBIL

Fr. Gerbille du Veld; Ger. Brants Nacktsohlen-Rennmaus

Gerbilliscus brantsii (Smith, 1836). Rept. Exped. Exploring Central Africa, p. 43. Ladybrand, E Free State, South Africa. ‘Tops of hills near sources of Caledon River’ near Lesotho border (see Meester *et al.* 1986).

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Synonyms: *breyeri*, *draco*, *griquae*, *humpatensis*, *joanae*, *maccalinus*, *maputa*, *miliaria*, *montanus*, *namaquensis*, *natalensis*, *perpallida*, *ruddi*, *tongensis*. Subspecies: three. Chromosome number: $2n = 44$, $FN = 66$ (as *Tatera brantsii*); karyotype identical to that of *G. afra* (Qumsiyeh 1986).

Description Medium-sized gerbil with darker dorsal surface, pale underparts and long tail. Dorsal pelage pale rufous-brown to pale reddish, with faint, uneven brown wash. Pelage soft and fluffy; hairs long and broad with narrow base and typical chevron pattern. Ventral pelage pure white to buffy-grey. Head narrow, with pointed nose and long vibrissae. Large eyes. Chin white. Ears elongated, dark brown, rounded at tips. Hindlimbs much longer than forelimbs, hindfeet long. Fore- and hindfeet pale, five digits each, Digit 5 on forefeet reduced. Tail long (ca. 106% of HB, shorter than HB in some individuals), similar in colour to dorsal pelage, or slightly darker for at least the proximal half; distal half white; white below. Auditory bullae well-developed. Nipples: $1 + 2 = 6$ or $2 + 2 = 8$.

Geographic Variation Dorsal pelage varies from pale in C Botswana, pale or distinctly reddish in south-western parts of distribution, to darker in south-east parts of distribution. Meester *et al.* (1986) recognize three subspecies:

- G. b. brantsii*: Lesotho, Eastern Cape and KwaZulu–Natal Provinces, South Africa and westwards to edge of Kalahari Desert. Buff-grey patches on chest; heavier molars.
- G. b. griquae*: Kalahari northwards to S Angola and W Zambia. Pure white ventral pelage; narrower molars; pale dorsal pelage.
- G. b. ruddi*: N KwaZulu–Natal Province, South Africa. Buff-grey ventral pelage; relatively long white-tipped tail; long hindfoot.

Similar Species

- G. leucogaster*. Brighter, sleeker fur; sharp line of delineation between flanks and ventral pelage; tail has distinct dark line on dorsal surface, never white-tipped.
- G. afra*. Ventral pelage pure white, tail evenly coloured to tip; confined to Western Cape Province, South Africa.

Distribution Endemic to Africa. South-West Arid and Highveld BZs, with marginal extension to southern Zambezan Woodland BZ. Recorded from S Angola, W Zambia, Botswana, E Namibia and South Africa. Limited distribution in N Zimbabwe and C Mozambique. Absent from extremely arid parts of W Namibia and W South Africa.

Gerbilliscus brantsii

Habitat Associated with sandy soils and sandy alluvium, with some cover of grass, scrub or open woodland. Also found in peaty soils around marshes and pans, sometimes using tunnels of mole-rats (*Cryptomys* spp.). Not normally found on heavy consolidated soils or very loose sandy soils.

Abundance Common. In N Transvaal Province, South Africa, Brant's Gerbils were the commonest species in the dry season (May–Jun): in ‘old field’, density was 16/ha and biomass was 1280 g/ha (ca. 80% of total numbers and biomass; $n = 5$ spp. of small terrestrial rodents) and in *Burkea* woodland, density was 12/ha and biomass was 960 g/ha (ca. 75% of total, $n = 6$ spp.) (Korn 1987). In southern African highlands, estimated density was 14.8/ha (Feb) and 27.1/ha (May) (De Moor 1969).

Adaptations Highveld Gerbils are strictly nocturnal with crepuscular peaks of activity. Move by quadrupedal saltation. They excavate complex burrows in loose, sandy soil. A burrow has many entrances, and tunnels (ca. 45–60 mm in diameter) that interconnect underground. Maximum depth of burrows about 20 cm; total length of burrow systems about 6 m. There is one nesting chamber, sealed with loose sand, in each burrow system.

Foraging and Food Highveld Gerbils eat mostly plants, including roots and green parts, with insects comprising about 5% of diet in southern Kalahari. More green than white plant material is eaten in hot season, depending on rainfall (Nel 1978). Gerbils may have significant effects on local vegetation: plant biomass, root biomass and vegetation height is significantly lower, and species diversity and evenness of plants significantly higher, near old colonies than in adjacent, undisturbed areas. Highveld Gerbils maintain high plant diversity in savanna habitats (Korn & Korn 1989). Gut morphology is simple and unspecialized suggesting a general opportunistic diet (Perrin & Curtis 1980).

Social and Reproductive Behaviour Colonial, with several individuals living in close proximity to others. Adults are rarely aggressive towards each other in laboratory encounters. If aggression does occur, both animals stand up on hindfeet, and strike at each other with their forepaws. Copulation consists of a series of mounts with and without intromission, culminating in intromission with ejaculation. No lock; copulatory plug deposited after ejaculation. Multiple copulations and ejaculations occur over about an hour.

Vocalizations include two kinds of ultrasonic whistles: short whistles of 17–27 kHz lasting about 157 msec, and long whistles of 17–31 kHz, lasting about 480 msec (Dempster & Perrin 1991b).

Reproduction and Population Structure Pregnant ♀♀ recorded throughout year, with peak of reproductive activity at onset of cool dry season (Gauteng Province, South Africa). Males show active spermatogenesis throughout year, with peak in warm wet season. Breeding strategy similar to that of other gerbils: short gestation, altricial young, iteroparous, but small litter-size. Gestation: 22 days. Embryo number: 2.8 (1–5). Mean litter-size: 2.8. Mean weight at birth: 4.6 g. Growth rate in first 28 days: 1.1 g/day. Pups cling to nipples from Day 1–4. Incisors erupt Day 6. Eyes open Day 16–20. Weaned by Day 28 (Scott 1979). Postpartum oestrus indicated by 40% of ♀♀ in the wild being both lactating and pregnant. Females may have five or six litters/year (Measroch 1953). Testes in adult ♂♂ are large, comprising ca. 5% of adult body weight (Allanson 1958; cf. *G. afra*).

Predators, Parasites and Diseases Preyed on by snakes, small mammalian carnivores, Barn Owls *Tyto alba* and African Grass-owls *Tyto capensis*. Wild populations sometimes afflicted by *Yersinia pestis*, leading to local outbreaks of bubonic plague. Susceptible to infection by *Pseudomonas pseudomallei*, *Listeria monocytogenes* and *Mycobacterium tuberculosis* in the laboratory. Endoparasites include the cestodes *Hymenolepis microcantha*, *H. taterae* and *Raillietina trapezoides*. Ectoparasites include 29 species of fleas and nine species of ticks (details in De Graaff 1981). Widely used as a laboratory animal for medical research.

Conservation IUCN Category: Least Concern.

Edith R. Dempster

Gerbilliscus gambianus GAMBIAN GERBIL

Fr. Gerbille de Gambie; Ger. Gambische Nacktsohlen-Rennmaus

Gerbilliscus gambianus (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 6: 428. Marakissa, Upper Gambia, Senegal.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Often considered to be a synonym of *G. kempi* (e.g. Rosevear 1969, Musser & Carleton 1993, 2005) or *G. validus kempi* (Bates 1988). Re-established as a distinct species by Hubert *et al.* (1973) following Matthey & Petter (1970). Distinguished by karyotype from other *Gerbilliscus*. Synonyms: *hopkinsoni*. (The form *hopkinsoni* was described later from the same region as *gambianus* [Gambia R], but this name was given improperly by various authors to specimens with 2n = 48, a karyotype never found in this region.) Subspecies: none. Chromosome number: 2n = 52, aFN = 64 (Matthey & Petter 1970; as *T. gambianus*).

Description Large robust gerbil. Dorsal pelage grey-brown; hairs dark grey at base, with wide brown or orange central zone, black at tip. Flanks paler; hairs without black tip. Ventral pelage white, clearly delineated from colour of flanks. Head rounded, similar in colour to flanks. Moderately pointed nose. Large eyes; moderately elongated ears. Chin, throat, chest and inner sides of limbs white. Hindfeet white above, dark below; forefeet entirely white. Tail moderately long (ca. 80–100% of HB), well haired, dark above, orange to brown on sides, white below, without any marked pencil of hairs at terminal end. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

G. kempi. Ear on average longer; chromosome number: $2n = 48$. More southern distribution; other species of this short-tailed group occur only in eastern and southern Africa.

G. guineae. Tail on average longer (110–140% of HB) with pencil. $2n = 50$. Similar distribution.

Distribution Endemic to Africa. Sahel Savanna and Sudan Savanna BZs of Senegal (Hubert *et al.* 1973) and Mali (B. Sicard & L. Granjon unpubl.). Recent captures in SE Niger (Kojimairi, 40 km south of Goudoumaria; Dobigny *et al.* 2002b) and at the southern edge of L. Chad (Granjon & Dobigny 2003) suggest a much larger range.

Habitat In Senegal, found in *Combretum* woodlands (where sympatric with *G. guineae*), but on soils that are more sandy. Also trapped in fallow lands and traditionally cultivated fields (Hubert 1977, Hubert *et al.* 1977). The only species of gerbil found on sandy and mangrove islands in the Saloum Delta, Senegal (Granjon & Duplantier 1989).

Abundance Very varied according to habitat. Density up to 15/ha in sahelo-sudanian woodland at Bandia, Senegal, where may represent up to 17% of the rodents in favourable habitats (Hubert 1977). In the Saloum Delta, abundance varied from 3.5 to 24 individuals/ha on a 2 ha study area during a two-year survey (Granjon *et al.* 1994). This species seems to show more pronounced variations in abundance than *G. guineae* in mainland Senegal.

Adaptations Terrestrial and nocturnal. Digs complex and moderately deep burrows (average 30 cm), with many entrances. Up to ten burrows can be found within the home-range of one individual (Hubert *et al.* 1977). Poor swimming abilities (Duplantier & Bâ 2001).

Foraging and Food Consumes seeds, but also large amounts of insects especially at the beginning of the dry season (Moro & Hubert 1983).

Social and Reproductive Behaviour Little information. Home-range 600–800 m². Mean successive recapture distance 12.5 m (max 21.5 m) during a period of 10–12 days; recapture distances smaller than for sympatric *G. guineae* in W Senegal. Considerable overlap in home-ranges between individuals of both sexes. Does not show agonistic or amicable behaviour towards other species (Hubert 1977).

Reproduction and Population Structure In W Senegal, pregnant ♀♀ recorded at end of wet season and first half of dry season (Sep–Feb) but no pregnancies recorded during second half of dry season and beginning of wet season (Mar–Aug). Gestation: 25 days. Litter-size: 2–6. Sexual maturity: 11–15 weeks (Hubert &

Gerbilliscus gambianus

Adam 1975). Monthly mortality rate up to 50% when population is decreasing (Hubert 1977).

Predators, Parasites and Diseases Remains found in pellets of Barn Owls *Tyto alba* from various localities in W Senegal (J.-M. Duplantier & L. Granjon unpubl.). Protozoan parasites include *Leishmania major* (Dedet *et al.* 1981) and *Borrelia crociduræ* (Trape *et al.* 1991). Arboviruses include Touré, Keuraliba, Gabek Forest and Koutango strains (Annual Reports of Pasteur Institute, Dakar).

Conservation IUCN Category: Least Concern.

Gerbilliscus guineae GUINEA GERBIL

Fr. Gerbille de Guinée; Ger. Guinea-Nacktschalen-Rennmaus

Gerbilliscus guineae (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 5: 351. Gunnal, Guinea-Bissau.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Referred by Davis (1975a) to *T. robusta* (now *Gerbilliscus robustus*), but generally considered as a valid species (Rosevear 1969, Bates 1985). Synonyms: *picta*. Subspecies: none. Chromosome number: $2n = 50$, $aFN = 64$ (Matthey & Petter 1970, as *T. guineae*).

Description Medium to large-sized robust rodent. Dorsal pelage grey-brown; hairs dark grey at base, brown to orange central zone, and usually with short black tip. Flanks and head paler; hairs mostly without black tip. Ventral pelage and inner sides of limbs white; ventral colour clearly delineated on lower flanks. Chin, throat and chest white. Head rounded with moderately pointed nose. Large eyes; relatively elongated ears. Hindfeet white above, dark below; forefeet entirely white. Tail relatively long (110–140% of HB), well haired, dark above, white below, with marked pencil of darkish hairs at terminal end. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

G. kempi. Tail relatively shorter without terminal pencil; chromosome number: $2n = 48$; similar distribution.

G. gambianus. Tail relatively shorter without terminal pencil; $2n = 52$; overlapping distribution (in the northern part of the range of *G. guineae*).

Distribution Endemic to Africa. Sudan and Guinea Savanna BZs, and Northern Rainforest–Savanna Mosaic. Recorded from Senegal (Hubert *et al.* 1973), Guinea-Bissau and Guinea (Ziegler *et al.* 2002), Burkina (Matthey & Petter 1970), Sierra Leone (Grubb *et al.* 1998), Côte d'Ivoire (Gautun & Petter 1972), Ghana (Rosevear 1969) and Togo (Robbins & Van der Straeten 1996). Not recorded from Gambia (Grubb *et al.* 1998).

Habitat In Senegal, mostly found in *Combretum* woodlands on lateritic to clay, hydromorphous soils where there is a dense shrub layer and variable herbaceous cover (Hubert *et al.* 1977). Also trapped in cultivated areas (Senegal, Hubert *et al.* 1977; Mali, B. Sicard unpubl.) and on bare ironstone hills (Gambia; Rosevear 1969).

Abundance Little information. Uncommon in W Senegal. Density of ca. 4/ha in sahelio-sudanian woodland at Bandia, Senegal; comprised 7.7–21% of rodents in favourable habitats (Hubert 1977).

Adaptations Terrestrial and nocturnal. Digs relatively deep (average 50 cm) and moderately complex burrows in heavy soils. Entrances are hidden by heaps of excavated earth (Hubert *et al.* 1977).

Foraging and Food No information.

Social and Reproductive Behaviour Home-range 1400–

*Gerbilliscus guineae*

1500 m². Mean recapture distance 21 m (max 38 m during 10–12 days); larger than for sympatric *G. gambianus* in W. Senegal (Hubert 1977).

Reproduction and Population Structure In a monthly survey from Jun 1971 to Mar 1973 in W Senegal (Hubert 1977), pregnant ♀♀ were found mainly during the wet season (Aug–Oct), but reproduction continued until the middle of the dry season (Jan–Feb) in 1972. Embryo number: 4–5. Monthly mortality rate up to 30%, less variable than in *G. gambianus*.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

L. Granjon & J.-M. Duplantier

Gerbilliscus inclusus GORONGOZA GERBIL

Fr. Gerbille de Gorongoza; Ger. Gorongoza-Nacktschuh-Rennmaus

Gerbilliscus inclusus Thomas and Wroughton, 1908. Proc. Zool. Soc. Lond. 1908: 169. Tambarara, Mozambique.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Synonyms: *cosensi*, *pringlei*. Subspecies: three. The form *pringlei* was described as a valid species (Hubbard 1970b), treated as a subspecies here and by Davis (1975a), and as a synonym by Musser & Carleton (1993, 2005). Chromosome number: not known.

Description Large gerbil with dark dorsal pelage, long hindfeet and long tail. Dorsal pelage ochraceous-buff, washed with black; hairs dark slate, ringed with ochraceous and tipped with black. Flanks paler than dorsal pelage. Ventral pelage white from chin to tail tip. Colour varies geographically (see below). Head narrow, with pointed nose, long vibrissae, sides of muzzle darker than head. Large eyes with black mark under each eye. Ears pinkish, almost naked, relatively short. Hindlimbs longer than forelimbs, hindfeet elongated. Forefeet and hindfeet off-white, five digits each, Digit 5 on forefoot reduced. Tail long (ca. 115% of HB), dark above, white below, occasionally white-tipped. Upper incisors deeply grooved, lower incisors ungrooved. Nipples: 1 + 2 = 6 or 2 + 2 = 8.

Geographic Variation Meester *et al.* (1986) recognize three subspecies:

G. i. cosensi: N Mozambique and E Tanzania.

G. i. pringlei: Muheza, Tanzania (05° 10' S, 38° 47' E; Hubbard 1970b). Dorsal pelage black, ventral pelage and feet pure white; tail usually equal to or shorter than head and body length; only known from type locality.

*Gerbilliscus inclusus*

G. i. inclusus: E Zimbabwe and Mozambique south of Zambezi R. Dorsal pelage very dark (from forehead to base of tail); flanks dark ochraceous-buffy or reddish.

Similar Species

G. leucogaster. Smaller; paler in colour, texture of fur sleeker.

Distribution Endemic to Africa, Zambezan Woodland BZ and parts of Coastal Forest Mosaic BZ in Mozambique, E Zimbabwe and S Tanzania (east of L. Malawi). Perhaps occurs in localities between the currently known ranges.

Habitat Sandy ground or sandy alluvium, often on fringe areas between dry and riverine woodland, confined to areas with a mean annual rainfall of >800 mm. Often associated with agricultural lands and forest fringes, but not recorded within forests. The subspecies *G. i. pringlei* recorded in dense grassland with moist, sandy soil.

Abundance Not known.

Adaptations Nocturnal and terrestrial. Moves by quadrupedal saltation. Burrows of *G. i. pringlei* have an entrance tunnel, one or two chambers, one of which contains the nest, one or two side tunnels and an escape tunnel (which may be 2–2.5 m from the main burrow) (Hubbard 1970b). Food has not been found in burrows.

Foraging and Food Seeds, fruit and insects in captivity (as *G. i. pringlei*; Hubbard 1970b).

Social and Reproductive Behaviour Appear to have identical habits to Bushveld Gerbils (*G. leucogaster*), with which they occur sympatrically, although always in smaller numbers (Smithers 1983). Simple burrow systems indicate a more solitary social structure than Bushveld Gerbils; burrows normally occupied by a single animal or a ♀ with young. Copulation (in *G. i. pringlei*) consists of single mount with intromission and ejaculation. Animals footdrum by pattering the hindfeet alternately when alarmed (Hubbard 1970b).

Reproduction and Population Structure No information on seasonality of breeding. Gestation: 23–24 days. Litter-size: 2–3. Young not known to nipple-cling. Eyes open at Day 16–20.

Predators, Parasites and Diseases Little information. No fleas recorded on *T. i. pringlei*.

Conservation IUCN Category: Least Concern.

Gerbilliscus kemp KEMP'S GERBIL (NORTHERN SAVANNA GERBIL)

Fr. Gerbille de Kemp; Ger. Kems Nachtsohlen-Rennmaus

Gerbilliscus kemp (Wroughton, 1906). Ann. Mag. Nat. Hist., ser. 7, 17: 375. Aguleri, Nigeria.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Sometimes included within *Tatera valida* (now *Gerbilliscus validus*) (e.g. Davis 1975a, Happold 1987, Bates 1988), but more generally considered to be a valid species (Rosevear 1969, Grubb *et al.* 1998). Synonyms: *beniensis*, *benvenuta*, *dichrura*, *dundasi*, *flavipes*, *lucia*, *nigrita*, *ruwenzorii*, *smithi*, *soror*; *gambiana*, *giffardi*, *hopkinsoni*, *welmani*. All except the last four were included as synonyms under *Tatera valida* (= *Gerbilliscus validus*) by Musser & Carleton (1993). Subspecies: none. Chromosome number: 2n = 36 (Matthey & Petter 1980, in Robbins & Baker 1978).

Description Medium-sized robust rodent with shaggy hair and tail slightly longer than head and body. Dorsal pelage sandy-grey to sandy-orange; dorsal hairs sandy with dark grey at base and usually with black tip. Flanks similar to dorsal pelage, hairs usually without dark tips. Ventral pelage pure white. Dorsal and ventral colours clearly delineated. Chin, throat, chest and inner sides of limbs white. Eyes large, head rounded with moderately pointed nose. Tail long (ca. 100% of HB), sparsely haired, dark above, white below, with small pencil of darkish hairs (often lost in adults) at terminal end. Juvenile pelage sandy-grey, usually duller and less sandy than in adults. Males tend to be larger than ♀♀. Each upper incisor with single groove. Nipples: not known.

Geographic Variation Individuals at southern part of range (within, or close to, the Rainforest BZ) have greater density of black-tipped hairs and appear darker than northern individuals.

Similar Species

G. validus. On average larger (HB: 167 [135–195] mm, HF: 34.0 [30–39] mm, GLS: 41.7 [38.5–44.7] mm); tail lacks pencil at terminal end; auditory bullae larger; distribution mainly in eastern Africa.

G. guineae. Similar size. Hindfoot on average longer; tail on average longer and relatively longer with well-developed pencil; distribution Senegal to Ghana and Togo.

Taterillus gracilis. Much smaller and more slender; tail relatively longer (ca. 130% of HB) covered with short bristles and well-developed pencil at terminal end; syntopic and sympatric.

Distribution Endemic to Africa. Guinea Savanna BZ and Northern and Eastern Rainforest–Savanna Mosaics. Recorded from

Gerbilliscus kemp

Gambia and Sierra Leone to Nigeria, and probably to S Sudan and NW Kenya; may sometimes extend northwards into parts of Sudan Savanna BZ in the east of the range. Sometimes found in savanna-like habitats on edge of rainforest. Recorded from coastal grasslands of the Dahomey Gap in Ghana (Grubb *et al.* 1998), Togo and Benin (Robbins & Van der Straeten 1996). Extent of geographic range in central and eastern Africa uncertain (see also *G. validus*).

Habitat Savanna grasslands where there is good cover of grasses and/or dense shrubs, and where the soil is sandy and friable for digging burrows. Also occur wherever there are farmlands and plantations, such as maize and cassava fields, cocoa and oil palm plantations, and abandoned farmlands with thick grassy cover.

Abundance One of the commonest rodents in suitable savanna habitats where the rainfall is 1000–1500 mm/year and where the wet season lasts for 7–8 months (Apr–Nov). In the Rainforest–Savanna Mosaic of Nigeria (7–8°N), comprised less than 10% of small terrestrial rodents. Likewise on the grasslands of the Shai Hills

(Accra Plains, Ghana, ca. 6° N), formed about 10% of small rodents (n = 27) (Decher & Bahian 1999), and also ca. 10% (n = 3906 trappable small rodents; third commonest of 13 spp.) at Fro-Fro (7° 55' N), Côte d'Ivoire. Relative abundance increases from south to north, and near Kainji N. P., Nigeria (09° 50' N) comprised nearly 100% of small rodents (Happold 1975b). Density up to 46/ha (= ca. 4.6 kg/ha) in Kainji N. P., Nigeria.

Adaptations Nocturnal and terrestrial. Kemp's Gerbils live in burrows during the day and forage above ground at night. They have strong limbs and wide hindfeet for digging and burrowing, and large eyes and well-developed auditory bullae for good sensory perception.

Foraging and Food Granivorous, herbivorous and opportunistic. The diet is primarily seeds, but also leaves, shoots and roots. In the dry season, insects are eaten when succulent foods unavailable. Kemp's Gerbils also feed on crops and may cause damage in farmlands. They collect and store seeds in their burrows. Stored seeds probably provide food at beginning of the wet season when other seeds are scarce (D. C. D. Happold unpubl.).

Social and Reproductive Behaviour Mostly unknown. High density of individuals in suitable habitats suggests overlapping home-ranges. Several individuals may be kept together in captivity without any signs of aggressive behaviour.

Reproduction and Population Structure Pregnant ♀♀ recorded in late wet season (Dec) in S Nigeria. Juveniles (25–50 g) abundant in dry season (Dec–Mar) in Kainji N. P., Nigeria. In C Côte d'Ivoire (07° 55' N), adult ♀♀ were reproductively active in most

months of the year, and pregnant ♀♀ were recorded in Feb, Mar, Jun, Oct and Nov (Gautun 1975). The limited evidence suggests that pregnancies occur at the beginning and end of the wet season, and rarely during the main part of the wet season. Mean litter-size: 2.7 (n = 9) in Feb/Mar and 6.0 (n = 10) in Oct/Nov (Gautun 1975; no ranges given).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

A common and widespread species in suitable savanna habitats.

Gerbilliscus leucogaster BUSHVELD GERBIL

Fr. Gerbille à ventre blanc; Ger. Weissbauch-Nacktsohlen-Rennmaus

Gerbilliscus leucogaster (Peters, 1852). Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin, p. 274. Mesuril and Boror, Mozambique.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Synonyms: *angolae*, *bechuanae*, *beirae*, *beirensis*, *kaokoensis*, *limpopoensis*, *littoralis*, *lobengulae*, *mashonae*, *mitchelli*, *ndolae*, *nigrotibialis*, *nyasae*, *panja*, *pestis*, *pretoriae*, *salsa*, *schinzi*, *shirensis*, *stellae*, *tenuis*, *tzaneenensis*, *waterbergensis*, *zuluensis*. Subspecies: none. Previously, 17 of these forms from the southern African region were considered to be subspecies, but their distribution is contiguous and populations of these forms integrate evenly throughout their range. Chromosome number: 2n = 40, FN = 66 (Qumsiyeh, 1986).

Description Medium-sized gerbil with white underparts, darker dorsal surface and very long tail. Dorsal pelage reddish-brown to orange-buffy, depending on geographical area. Dorsal hairs slate-grey on basal two-thirds, changing to buffy-white, then pale rufous-buff at tip. Ventral pelage pure white from chin to tail tip. Head narrow, with pointed nose, long vibrissae, sides of muzzle white. Large eyes with white mark above and behind each eye. Ears elongated, dark brown, rounded at tips. Hindlimbs much longer than forelimbs, elongated hindfeet. Fore- and hindfeet pure white, five digits each, Digit 5 on forefoot reduced. Tail relatively long (ca. 115% of HB),

covered with dense short hairs, distinct brownish band down entire length on dorsal surface, white underneath, often darker terminal tuft. Anterior face of incisors grooved, lower incisors ungrooved. Auditory bullae well developed. Nipples: 2 + 2 = 8, but considerable variation.

Geographic Variation Dorsal pelage ranges from bright cinnamon-buff in west to reddish-brown in east.

Similar Species

G. brantsii. Pelage softer and fluffier; tail without distinct dark line, usually white at tip.

Distribution Endemic to Africa. Widely distributed in the Zambezi Woodland BZ, parts of the South-West Arid BZ (Kalahari Desert) and Highveld BZ. Northern limits uncertain, probably ca. 6° S. Widespread in Angola, S DR Congo, Zimbabwe, S Tanzania, Malawi, Mozambique, Namibia, Botswana and N South Africa. Southern limit in South Africa about 30° S, including the lowveld of Swaziland and NE KwaZulu–Natal Province.

Habitat Predominantly associated with open grasslands and wooded savannas on light sandy soils or sandy alluvium. Common on sandy plains along dry river courses in C Namib, in miombo woodland in Zimbabwe and woodland savanna in Malawi. Absent from areas of heavy red clay soils or soft sand. Generally restricted to areas with mean annual rainfall above 250 mm, although in Namibia occur in areas with mean annual rainfall less than 100 mm. Occur at altitudes of sea level to ca. 1600 m.

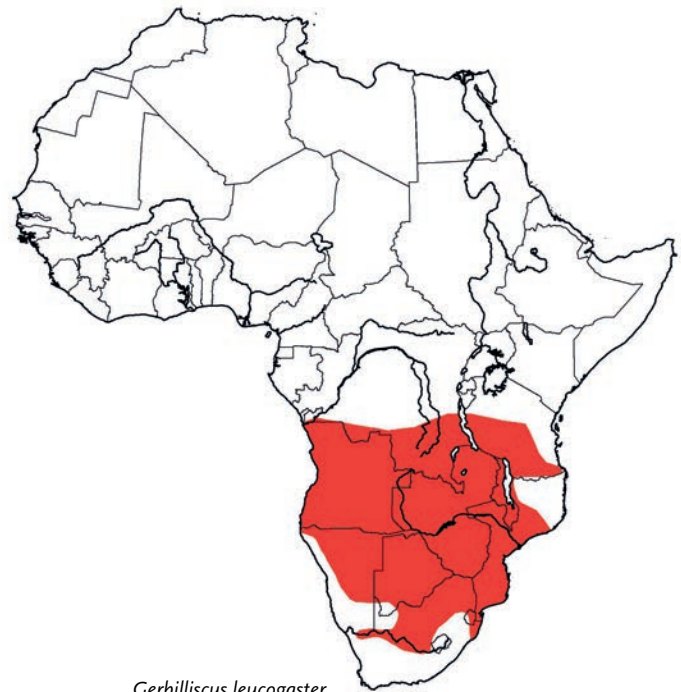

Abundance Abundance varies according to locality, vegetation and time of year. At Sengwa, Zimbabwe, number of individuals was 1.9–7.0/ha in *Brachystegia* woodland, 0.8–2.3/ha in thicket habitats and 0–1/ha in riverine grasslands (Linzey & Kesner 1997a). Percentage abundance was 70–90% (cool dry season) and ca. 86% (other seasons) in *Brachystegia* woodland (where it was always the most numerous species), 56–100% (cool dry season) and 67% (hot wet season) in thicket habitats, and 0% (most seasons) to 3% (cool dry season) in riverine grasslands. At Nylsvley, South Africa, percentage abundance varied during the dry season from 6% (in old fields, where it was the least common of the five species present) to 61% (in burnt *Acacia* woodland where it was the commonest of five species present) (Korn 1987). In Liwonde N. P., Malawi, comprised 18% of small terrestrial rodents ($n = 106$; 7 spp.) and was encountered only during the dry season (Happold & Happold 1990). The frequency of burning, and when burning occurs, has a considerable effect on the numbers of individuals and their percentage occurrence within the community of small mammals; in general formed higher proportions of the small mammal community in habitats that had been burnt at one or more times during the last three years than in unburnt control habitats (Korn 1981). De Graaff (1981) comments that ‘populations are subject to cyclic explosions in numbers’, but does not give quantitative data to support this statement.

Adaptations Nocturnal and terrestrial. Moves by quadrupedal saltation. Excavates burrows, which are about 40–45 mm in diameter, with the entrance at the base of small bushes or grass clumps. Burrows are complex with many entrances and tunnels that interconnect underground. Burrow systems include chambers lined with vegetable debris.

Bushveld Gerbils have many physiological characters concomitant with survival in hot, arid environments, although they are less arid-adapted than other gerbil species. Basal metabolic rate and evaporative water loss is lower than in mesic rodents, minimal wet thermal conductance is about the same as expected for body mass, resting body temperature below thermoneutrality is lower than in mesic rodents, and the thermoneutral zone is broader than in more xeric-adapted gerbil species (Downs & Perrin 1994, Webb & Skinner 1996a).

Foraging and Food Bushveld Gerbils eat insects, seeds and herbage. Individuals in N South Africa eat mostly insects and seeds during warm wet season, and lose weight in cool dry season when eating mostly herbage. No seasonal variation in diet in Zimbabwe.

Social and Reproductive Behaviour Social structure unknown, but burrows often clumped, and several individuals trapped from a single burrow system indicate a tolerant social structure. Adults rarely aggressive towards each other in laboratory encounters.

Gerbilliscus leucogaster

Copulation consists of series of mounts with and without intromission, culminating in intromission with ejaculation; there is no lock and a copulatory plug is deposited after ejaculation. Multiple copulations and ejaculations occur over about an hour. Vocalize audibly between 5.5 kHz and 4.8 kHz; ultrasonic whistles begin at 48 kHz, descending to a trill at about 30 kHz; short ultrasonic ‘peeps’ emitted at about 40 kHz and 63 kHz. Males perform a post-copulatory song, which consists of series of whistles beginning at about 50 kHz, descending to about 15 kHz, and lasts about one minute. Animals footdrum when alarmed. Hindfeet patter alternately in bursts of 6–10 beats (Dempster & Perrin 1994).

Reproduction and Population Structure Breeding occurs throughout the year, with peaks in Dec–Jan and Apr–May, associated with rainfall. Second breeding season in dry season reported in parts of Zimbabwe, elsewhere breeding ceases in cool dry season. Breeding strategy similar to other gerbil species: short gestation, large litter-size, altricial young, iteroparous (Perrin & Swanepoel 1987). Gestation: 28 days. Embryo number: 4.5 (2–9) over range of habitats. Mean litter-size: 5.0. Mean birth-weight: 3.6 g. Growth rate in first 32 days: 0.9 g/day. Young do not nipple-cling. Incisors erupt Day 5–6. Eyes open Day 16–21. Young weaned by Day 28. Annual reproductive capacity of ♀♀ is 28 young/year in mixed woodland habitat, and 12 young/year in miombo woodland habitat (Neal 1991). Testis mass of adult ♂♂: ca. 6% of total body weight, larger than most other rodent species. Testes of many ♂♂ regress during dry season. Sex ratio not significantly different from parity. Juveniles enter the population during the warm wet season, and population numbers decline in dry season; seasonal changes in population structure are variable.

Predators, Parasites and Diseases Recorded as a prey item of the Barn Owl *Tyto alba*. Susceptible to infection of the neurotropic strain of African horse sickness and *Listeria monocytogenes* under laboratory conditions. Recorded as a reservoir of the plague bacillus *Yersinia pestis*.

in South Africa and DR Congo. Fleas include 25 species in the families Hystrichopsyllidae, Chimaeropsyllidae and Pulicidae (details in De Graaff 1981). In East Africa, Bushveld Gerbils carry three species of fleas of their own: *Xenopsylla debilis*, *X. humilis* and *X. difficilis*.

Conservation IUCN Category: Least Concern.

Abundant throughout its geographic range.

Edith R. Dempster

Gerbilliscus nigricaudus BLACK-TAILED GERBIL

Fr. Gerbille à queue noire; Ger. Schwarzschanz-Nacktschalen-Rennmaus

Gerbilliscus nigricaudus (Peters, 1878). Monatsber. K. Preuss. Akad. Wiss. Berlin 1879: 200. (publ. 1878). Ndi, Taita, Kenya.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). This species, *G. robustus* and *G. validus* are closely related and sympatric in parts of their ranges. Although the all-black tail is the main character of *nigricaudus*, the tail of *G. robustus* is black (or partially black) in some parts of its range, especially in the northern part. The three species are difficult to differentiate with absolute certainty using external characters only; and some individuals ascribed to *nigricaudus* in the past are probably *G. robustus*. A combination of external measurements, colour and certain skull characters are necessary to separate these species from each other. Bates (1988) considered that *bayeri* (Mt Elgon and Karamoja) and *bodessae* (Ethiopia), both formerly considered to be subspecies of *G. nigricaudus*, are referable to *G. robustus*. Synonyms: *nyama*, *percivali*. Subspecies: two. Chromosome number: not known. The individuals referred to by Matthey (1969), for which he gave a chromosome number of 2n = 40, are considered to be *T. robusta* (now *Gerbilliscus robustus*) by Bates (1988).

Description Large brown gerbil with long black tail. Pelage long, soft and sleek. Dorsal pelage brown, suffused with black in some individuals; dorsal hairs pale grey at base, with ochre, brown or black at tip. Flanks paler; hairs white at base, pale ochre or sandy at tip. Ventral pelage white. Dorsal and ventral colours clearly delineated. Head and cheeks similar to dorsal pelage. Chin, chest, inner surfaces of limbs white. Hindfeet white; soles naked and darkly pigmented. Tail long (ca. 110% of HB), thickly covered with very dark brown or black bristles above and below; longer black hairs form small pencil at tip in some individuals; a few pale hairs may occur on undersurface, especially on distal third of tail; colours above and below merge laterally. Skull large; rostrum rounded and wide (cf. *G. robustus*); upper incisors opisthodont, each incisor with clearly defined single groove. Males larger than ♀♀ for most body and cranial measurements. Width of M¹ 2.4–2.5 mm. Nipples: not known.

Gerbilliscus nigricaudus

Geographic Variation Two subspecies are recognized (Bates 1988):

G. n. nigricaudus: NE Tanzania and S Kenya. Larger size; tail black above and below.

G. n. nyama (incl. *percivali*): N Kenya and Somalia. Smaller size; tail black above, with some pale hairs below, especially on distal third.

Similar Species

G. robustus. Smaller HB; tail brown, often with black at tip or on all of upper surface; often black/brown pencil at terminal end; no white tip to tail; skull on average smaller in all dimensions.

G. validus. HB on average smaller; tail brown, normally without any black, no white tip to tail, no pencil at terminal end; skull usually smaller.

G. boehmi. HB smaller; tail brown, usually longer (actual length and relative to HB), white at terminal end; skull usually smaller.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Savanna woodlands and grasslands of C and N Kenya east of the Rift Valley, extreme NE Tanzania, S Somalia and S Ethiopia.

Habitat Savanna woodlands with bushy thickets and scattered *Acacia*, *Stercularia* and *Terminalia* trees; also open grassy plains dominated by *Chrysopogon*, *Sehima* and other grasses (Meru N. P., Kenya; Neal 1984b). Habitat shows seasonal changes in cover and productivity; rainfall is bimodal with two wet seasons per year.

Abundance Distribution patchy, although probably relatively common in suitable habitats.

Adaptations Nocturnal and terrestrial. Individuals exhibit rapid response to seasonal changes in food availability (caused by seasonal changes in rainfall, number of arthropods and plant growth), which, in turn, regulates reproductive cycle (see below).

Foraging and Food Omnivorous and opportunistic. Pronounced seasonal changes in diet. In the dry seasons (in Meru N. P., Kenya; Neal 1984b) arthropods (mainly insects) comprise the main proportion of the diet (ca. 90%), with smaller amounts of seeds (1–9%) and forbs (1–3%). In the wet seasons, the proportion of arthropods drops (50–70%), and the proportions of grasses and sedges (3–13%), forbs and browse (13–20%) and seeds (7–23%) increase. In the period after the wet season and before the dry season begins, when the grasses have set seed, the diet is mainly seeds (53–62%) and insects (30–35%) with hardly any grass or forbs (Neal 1984a). Gerbils utilize the foods that, at each season, are common and provide the best source of energy and protein. The diet was similar to that of parapatric *Acomys wilsoni* and *Gerbilliscus robustus* (as *Tatera robusta*), which suggests possible competition for food between these species (Neal 1984a).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Seasonal reproduction, with two periods of breeding each year, correlate with the bimodal pattern of rainfall. Reproductive activity (pregnancies, number of corpora lutea in ovaries) was maximum during each of the two wet seasons per year (Nov–Jan, Apr–May), declined during the

early dry seasons and ceased at the end of each dry season (Sep and Mar) (Meru N. P., Kenya; Neal 1982). Weight of testes greater during and immediately after wet season than during dry season; no evidence that ♂♂ sexually inactive at any time of year. Embryo number: 5.22 (1–8, n = 37 litters). Litter-size increases with increasing maternal weight, and mean litter-size (regardless of maternal size) is higher in wet season (5.5) than in early dry season (4.2). Pregnancy rate: up to 50% of adult ♀♀ pregnant during wet seasons. Females may have three litters/year, and a reproductive capacity of up to 24 young/year (Neal 1982). Young conceived and born during wet seasons are recruited into the trappable population in Jan–Feb and Jul–Aug; maturity is attained by beginning of following wet season. Young born in early dry seasons fail to contribute to the population (perhaps due to early mortality?).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Measurements

Gerbilliscus phillipsi PHILLIPS'S GERBIL

Fr. Gerbille de Phillips; Ger. Phillips Nacktsohlen-Rennmaus

Gerbilliscus phillipsi (de Winton, 1898). Ann. Mag. Nat. Hist., ser. 7, 1: 253. Hanka Dadi, Somalia.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). Often considered to be a subspecies of *G. robustus*, but raised to specific level by Bates (1985, 1988) on the basis of size (see also Musser & Carleton 1993). Synonyms: *bodessana*, *umbrosa* and probably *miniscula* (see Bates 1988). Subspecies: none. Chromosome number: not known.

Description Medium-sized gerbil, similar to *G. robustus*. Smallest species of *Gerbilliscus* in eastern Africa. Dorsal pelage pale brown to orange-brown, darker on lower back and rump; hairs grey at base, with dull pale orange-brown subterminal band and (especially on rump) black tip. Flanks paler, with fewer black-tipped hairs. Ventral pelage pure white, clearly delineated from colour of flanks. Lips, cheeks, throat and chest pure white. Ears large, slightly pigmented. Forefeet white above; five digits; Digits 1 and 5 short. Hindfeet white above; soles with brown pigment; Digit 1 short, not reaching base of other digits; Digits 2, 3 and 4 long, Digit 5 shorter; all digits with short pointed claws. Tail long (ca. 128% of HB), bicoloured, pale orange-brown above, white below; some black hairs above towards terminal end but without pencil or tuft. Skull: smaller than that of *G. robustus* (as *T. robusta*; Bates 1988).

Geographic Variation Populations in Kenya have darker pelage than those further north in Ethiopia and Somalia (Bates 1985).

Similar Species

G. robustus. On average larger in body and skull measurements (HB: 152.2 [120–190] mm; GLS: 41.9 [39.0–44.7] mm; GWS: 21.1 [19.5–22.4] mm). Tail usually with pencil.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from NC Kenya, Ethiopia (Rift Valley) and Somalia.

Habitat Dry arid savanna, and semi-desert. In the Omo Valley of Ethiopia (Hubert 1978b) populations (recorded as *Tatera nigricauda*) occur in the treeless grasslands and thickets where the soils are heavy and clay-like; these grasslands are seasonally flooded. On the lower slopes of the valley they live in very arid habitats of tuffs and recently eroded sediments, which support a sparse arid vegetation (e.g. *Euphorbia*, *Adenium*).

Abundance The species has been recorded at only nine localities (Bates 1988). In the Omo Valley, Ethiopia, comprised 21% of small trappable rodents in tree and shrub habitats near the river (total $n = 19$, 4 spp.), 20% in grasslands near the river (total $n = 53$, the second most numerous of 8 spp.) and 6% in the arid habitats (total $n = 30$; 6 spp.).

*Gerbilliscus phillipsi*

Remarks Only found in dry habitats, so evidently well adapted to high temperatures and a lack of free water. Recorded in the same habitat in the Omo Valley as *Acomys wilsoni*, *Saccostomus mearnsi* and *Mastomys erythroleucus* (in grasslands), and *Taterillus harringtoni*, *Arvicanthis somalicus*, *Gerbillus pusillus* and *Xerus rutilus* (in arid habitats) (Hubert 1978b).

Conservation IUCN Category: Least Concern.

D. C. D. Happold

***Gerbilliscus robustus* FRINGE-TAILED GERBIL**

Fr. Gerbille robuste; Ger. Fransenschwanz-Nacktsohlen-Rennmaus

Gerbilliscus robustus (Cretzschmar, 1826). In: Rüppell, Atlas Reise Nordl. Afrika, Zool. Säugeth. 1: 75. Ambukol, Sudan.

Taxonomy Originally described in the genus *Tatera* (see profile Genus *Gerbilliscus*). The species of *Gerbilliscus* in eastern Africa – *G. robustus*, *G. validus*, *G. nigricaudus* and *G. phillipsi* – are morphologically similar, and positive identification requires consideration of a number of characteristics (see Table 23). Colouration of tail and length of hindfoot are not good diagnostic characters by themselves. The similarity between this species and *G. nigricaudus* has resulted in some specimens of *G. robustus* being incorrectly identified as *G. nigricaudus* (e.g. Delany 1964a, Hubert 1978b). This species is closely related to *G. validus*, and the two may, in fact, represent a single polymorphic species (D. Kock pers. comm.). Synonyms: *bayeri*, *bodessae*, *iconica*, *loveridgei*, *macropus*, *mombasae*, *muansae*, *pothae*, *shoana*, *swathlingi*, *taylori*, *vicina*. Subspecies: none. Chromosome number: $2n = 40$, $FN = 70$ (Omo Valley, Ethiopia; Bates 1988 as *T. robusta*).

Description Large dark-coloured gerbil. Pelage long and soft. Dorsal pelage dark brown, flecked with black. Dorsal hairs (12–15 mm long) grey at base, with cinnamon, dark brown or black tip. Flanks paler, orange-brown, with fewer black-tipped hairs. Ventral pelage pure white. Dorsal and ventral colours clearly delineated. Head blackish-brown, with sandy-brown cheeks. Eyes large, sometimes with black eye-rings. Black vibrissae. Ears large, rounded and naked. Chin, throat, neck and chest pure white. Fore- and hindlimbs pale brown above, white below. Soles of hindfeet naked, darkly pigmented. Tail long (ca. 115% of HB), thickly covered with small short hairs; colour varied – brown with varying amounts of black to nearly all black, usually with pencil of hairs on terminal third; paler below; upper and lower colours usually clearly delineated (see details below). Skull: rostrum long and narrow; width of M^1 : 2.0 (2.0–2.4) mm (cf. *G. validus*; see Table 23). Sexes similar in size. Nipples: not known.

Geographic Variation Dorsal pelage varies in different parts of geographic range. Individuals from semi-arid areas of Sudan are paler than those from Kenya and Tanzania. Tail colour varies geographically. In southern part of range (Tanzania), brown above with some brownish-black or black hairs at terminal end or on terminal half; white, ochre or pale brown below; in northern part of range (Ethiopia), mostly or completely black above; ochre or brown below (and sometimes with black on the terminal third). Individuals intermediate between these extremes in central part of range. Individuals with dark tails appear very similar to *G. nigricaudus* although, in most individuals, the tail is not pure black above and below as in *G. nigricaudus* (Bates 1985). The large amount of variation in this species was responsible for each variant being described originally as a new species (see synonyms).

Similar Species

G. validus. Slightly larger on average; tail ca. 95% of HB, usually without any black colouration; width of M^1 usually >2.5 mm.

G. nigricaudus. Tail ca. 100% of HB, always black above and below; width of M^1 2.4–2.5 mm.

*Gerbilliscus robustus*

G. phillipsi. On average smaller size; tail ca. 130% of HB, orange-brown above; width of $M^1 <2.1$ mm.

Distribution Endemic to Africa. Widespread in Somalia–Masai Bushland BZ, and in eastern parts of Sahel Savanna and Sudan Savanna BZs. Recorded from Tanzania, Kenya, Somalia, Ethiopia (below 1700 m) and Sudan. Probably extends westwards to Chad (and perhaps Burkina – see Bates 1985; Musser & Carleton 1993, 2005).

Habitat Savanna grassland plains, *Acacia* bush, *Salvadora* thickets and grassy edges close to forest. In Ethiopia, lives in arid habitats at lower altitudes (below ca. 1600 m). In Serengeti, Tanzania, habitats on the higher levels of a catena are preferred to those at the base of a catena which are flooded during the wet season (Senzota 1984). In Sudan, found in semi-arid sandy soils with sparse vegetation. Tends to prefer loose soils suitable for burrowing.

Abundance Very varied. Recorded as ‘numerous’ in Serengeti, Tanzania (Misonne & Verschuren 1966). The number of burrows in Serengeti (Senzota 1984) suggests high populations in suitable habitats. In some habitats in Turkana, Kenya, recorded as the second most numerous species (after *Arvicanthis* sp.) with densities of up to 4860 individuals/km² (= 48 ind/ha) and biomass of 287 kg/km² (= 2870 g/ha) (Coe 1972). In Karamoja, Uganda (as *Tatera nigricauda*) formed 4% of trappable small rodents (total $n = 51$; Delany 1964a).

Adaptations Nocturnal and terrestrial. An adaptable species living in a wide range of savanna habitats. Constructs burrows with

multiple tunnels and entrances up to 60 cm below the surface; a single burrow system may cover an area of 3×2 m. Entrances are marked by spillheaps, which kill the grasses and herbs buried under the spillheap. In areas of high populations, spillheaps may cover 2% of the land area (Senzota 1984). Composition of diet suggests flexibility in feeding, and also that free water is not required when conditions are dry. Very high rainfall and flooding in low-lying habitats may result in mortality when burrows are flooded. Species that live syntopically with *G. robustus* in Ethiopia include *Mastomys erythroleucus*, *Saccostomus mearnsi* and *Acomys wilsoni* (in grassy riverine habitats with thickets) (Hubert 1978b), and *Arvicanthus niloticus*, *Acomys subspinosus*, *A. dimidiatus* and *Saccostomus mearnsi* in Kenya (Bates 1988).

Foraging and Food Omnivorous. On the Rojewero Plains, Kenya, the diet (expressed as mean % density of fragments in stomach contents, $n = 7$ stomachs) was 57% seeds, 29% arthropods, 12% grass and sedge, and 5% insects (Neal 1984a). In Turkana, Kenya (a drier habitat), diet was soft fruits 26%, seeds 26%, coarse plant material 21%, leaves and flowers 13% and insects 14% (Coe 1972). These gerbils probably forage opportunistically and the diet changes seasonally (as for other species of *Gerbilliscus*).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure In Kenya, reproduction is seasonal, with two periods of reproduction each year (as for *G. nigricaudus*), and is correlated with the bimodal pattern of rainfall. Pregnancies (counts and inferred by lactation) recorded in Jul–Aug and Nov–Jan. Embryo number 4.69 (2–7, $n = 13$) (Neal 1982). In Turkana (Coe 1972), and no doubt elsewhere, reproduction is very responsive to seasonal and annual variations in rainfall and climate.

Predators, Parasites and Diseases Preyed on by Spotted Eagle-owls *Bubo africanus* in Awash N. P., Ethiopia (Demeter 1982). Analysis of owl pellets showed that these gerbils comprised the largest number of individual prey items (27%) and the greatest mass of the prey (62%) in the diet. Also preyed on by small carnivores such as jackals in Serengeti, Tanzania.

Conservation IUCN Category: Least Concern.

Considered to be a pest in some localities where it feeds on crops such as cassava and groundnuts (Senzota 1984).
